FOREWORD

Aeronautical Radio, Inc., the AEEC, and ARINC Standards

ARINC organizes aviation industry committees and participates in related industry activities that benefit aviation at large by providing technical leadership and guidance. These activities directly support aviation industry goals: promote safety, efficiency, regularity, and cost-effectiveness in aircraft operations.

ARINC Industry Activities organizes and provides the secretariat for international aviation organizations (AEEC, AMC, FSEMC) which coordinate the work of aviation industry technical professionals and lead the development of technical standards for airborne electronic equipment, aircraft maintenance equipment and practices, and flight simulator equipment used in commercial, military, and business aviation. The AEEC, AMC, and FSEMC develop consensus-based, voluntary standards that are published by ARINC and are known as ARINC Standards. The use of ARINC Standards results in substantial technical and economic benefit to the aviation industry.

There are three classes of ARINC Standards:

- a) ARINC Characteristics – Define the form, fit, function, and interfaces of avionics and other airline electronic equipment. ARINC Characteristics indicate to prospective manufacturers of airline electronic equipment the considered and coordinated opinion of the airline technical community concerning the requisites of new equipment including standardized physical and electrical characteristics to foster interchangeability and competition.
- b) ARINC Specifications – Are principally used to define either the physical packaging or mounting of avionics equipment, data communication standards, or a high-level computer language.
- c) ARINC Reports – Provide guidelines or general information found by the airlines to be good practices, often related to avionics maintenance and support.

The release of an ARINC Standard does not obligate any organization or ARINC to purchase equipment so described, nor does it establish or indicate recognition or the existence of an operational requirement for such equipment, nor does it constitute endorsement of any manufacturer's product designed or built to meet the ARINC Standard.

In order to facilitate the continuous product improvement of this ARINC Standard, two items are included in the back of this volume:

An Errata Report solicits any corrections to existing text or diagrams that may be included in a future Supplement to this ARINC Standard.

An ARINC IA Project Initiation/Modification (APIM) form solicits any proposals for the addition of technical material to this ARINC Standard.

1.0 INTRODUCTION

1.0 INTRODUCTION

1.1 Purpose of this Document

This document defines the air transport industry standards for the transfer of digital information between avionics system elements. Adherence to these standards is desired for all inter-systems communication in which the Line Replaceable Units (LRUs) are defined by the relevant ARINC Characteristics. The use of these standards for intra-system communication is not necessary, although it may be convenient.

1.2 Organization of ARINC Specification 429

ARINC Specification 429: *Digital Information Transfer System (DITS)* is published in four parts:

- Part 1 Functional Description, Electrical Interfaces, Label Assignments and Word Formats
- Part 2 Discrete Word Data Formats
- Part 3 File Data Transfer Techniques
- Part 4 Archive of ARINC 429 Supplements

Part 1 provides the basic description of ARINC 429 functions and the supporting physical and electrical interfaces. Data word formats, standard label and address assignments, and examples are provided.

Part 2 defines ARINC 429 discrete words and bit assignments in label order.

Part 3 describes ARINC 429 data transfer protocols and message definitions for data transferred in large blocks and/or file format.

Part 4 is an archive of the ARINC 429 Part 1 Supplements (1 to 17) as published over the years. It was introduced as part of the update to ARINC 429 by Supplement 18, the 35th anniversary publication (2012).

Each part of ARINC Specification 429 is published independent of the others. The dash numbers assigned to each part are not intended to be synchronized.

Therefore, the latest version of ARINC Specification 429 Part X should be used when designing or procuring equipment.

1.3 Relationship to ARINC Specification 419

ARINC Specification 419: *Digital Data System Compendium* is a catalog of several early digital data transmission interfaces that have found application during the emergent period of digital avionics technology. The use of digital buses in the early days demonstrated a clear need for a general purpose digital information transfer system standard. ARINC Specification 429 draws on the experience gained from ARINC Specification 419, but is otherwise separate and distinct from it.

1.4 Digital Information Transfer System - Basic Philosophy

This document describes a method in which an avionics system element having information to transmit does so from a designated output port, over a single twisted shielded pair of wires, to all other system elements having need of that information. Bi-directional data flow on a given twisted and shielded pair of wires is not permitted.

1.0 INTRODUCTION

1.4.1 Numeric Data Transfer

ARINC 429 numeric data transmission characteristics have been developed from many successful methods of digital information transfer used in industry. Data for transmission is encoded in either two's complement fractional Binary (BNR) notation or in Binary Coded Decimal (BCD) notation. The data is supplied from source systems at data rates sufficiently high to ensure small incremental value changes between updates. Transmission is made open-loop, i.e., sinks are not required to inform sources that information has been received.

A parity bit is transmitted as part of each data word to permit simple error checks to be performed by the sinks. These, together with data reasonableness checks which may be performed by the sinks, may be used to prevent the display or other utilization of an erroneous or suspect word. The inherently high integrity of the twisted and shielded wire transmission medium ensures that drop-outs are few. The low rates of change of the data ensure the drop outs, when they do occur, are of no consequence.

1.4.2 ISO Alphabet No. 5 (ISO 5) Data Transfer

In addition to the transfer of BNR and BCD numeric data, ARINC 429 can transfer alpha and numeric data encoded per ISO 5. The same broadcast transmission philosophy is used, even though system operation may differ slightly to accommodate the particular needs associated with this type of data. These differences are addressed individually in this document as they arise.

1.4.3 Graphic Data Transfer

A third type of data which may be handled by ARINC 429 is graphic data, i.e., the lines, circles, randomly positioned alpha/numeric text and other symbols used on a map and similar displays. The technique employed for this purpose can be basically similar to that used for ISO 5 alpha/numeric data transfer. **ARINC Characteristic 744A: Full-Format Printer with Graphics Capability** provides additional information and example graphic characters that may be transferred using ARINC 429.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

2.1 Message Related Elements

This section describes the digital data transfer system elements considered to be principally related to the message itself or the manner in which it is handled.

2.1.1 Direction of Information Flow

The information output of an avionics system element should be transmitted from a designated port (or ports) to which the receiving ports of other system elements in need of that information are connected. In no case does information flow into a port designated for transmission.

COMMENTARY

A separate data bus for each direction of transfer is used when data is required to flow both ways between two avionics systems elements (see Section 2.2.1).

2.1.2 Information Element

The basic ARINC 429 information element is a digital word containing 32 bits. There are five types of basic words:

- Binary (BNR)
- Binary Coded decimal (BCD)
- Discrete
- Maintenance (general)
- Acknowledgement, ISO 5, Maintenance (AIM)

Word formats for these words are shown in Attachment 6. The data handling rules are set forth in Section 2.3.1. When less than the full data field is needed to accommodate the information conveyed in a word in the desired manner, the unused bit positions should be filled with binary zeros or, in the case of BNR/BCD numeric data, valid data bits. If valid data bits are used, the information resolution may exceed that called for in this specification (See Section 2.1.6).

COMMENTARY

To permit the use of identical error-checking hardware elements in the handling of BNR and BCD numeric data words, the format for ARINC 429 BCD words differ from that used formerly for this type of data. Bit 32 is assigned to parity, Bits 31 and 30 to the sign/status matrix, Bit 29 is the Most Significant Bit (MSB) of the data field, and the maximum decimal value of the most significant character is 7.

Also, latitude and longitude can only be encoded in the ARINC 429 word with the formerly specified resolution of 0.1 minute of arc if Bits 9 and 10 are used for data rather than the SDI function described in Section 2.1.4 of this document, and the word is structured differently from the standard shown in Attachment 6. Restructuring the word involves limiting the maximum value of the most significant character to 1 and moving the remaining BCD characters towards the MSB by two bit positions. It is possible, however, that future latitude and longitude displays will not be the simple, dedicated read-out type for which BCD data is intended. More likely is the use of some form of

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

multiple-message display, with its own data processor using BNR data. If this proves to be the case, these special provisions for BCD encoding will not be required.

2.1.3 Information Identifier

The type of information contained in a word is identified by a six-character label. ARINC 429 label code assignments are shown in Attachment 1-1 to this document. The first three characters are octal characters coded in binary in the first eight bits of the word. The eight bits are used as follows:

- a. Identify the information contained within BNR and BCD numeric data words (e.g., DME distance, static air temperature, etc.) and
- b. Identify the word application for Discrete, Maintenance and AIM data

The last three characters of the six-character label are hexadecimal characters used to provide for identification of ARINC 429 bus source. Each triplet of hexadecimal characters identifies a unit with one or more ARINC 429 ports. Each three character code (and LRU) may have up to 255 eight bit labels assigned to it. The code is used administratively to retain distinction between unlike parameters having like labels assignments.

COMMENTARY

Some users desire a means for identifying label sets and buses associated with a particular equipment ID code. Octal label 377 has been assigned for this purpose. The code appears in the three least significant characters of the BCD word. The transmission of the equipment identifier word on a bus enables receivers attached to the bus to recognize the source of the information. Since the transmission of the equipment identifier word is optional, receivers should not depend on that word for correct operation.

In some ARINC 429 applications, a bus may be dedicated to delivering a single information element from a source to one or more identical sink devices. In such circumstances, the sink device designer might be tempted to assume that decoding the word label is not necessary. Experience has shown, however, that system development may need additional information elements to appear on the bus. If a sink device designed for service prior to such a development cannot decode the original word label, it cannot differentiate between this word and the new data in the new situation. The message for sink designers should therefore be quite clear - provide label decoding from the outset, no matter how strong the temptation to omit it might be.

COMMENTARY

Adherence to the label code assignments of Attachment 1-1 is essential to ensure proper inter-system and intra-system communications. The assignment of ARINC 429 label codes is coordinated by ARINC Industry Activities (IA) for the air transport industry.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

When a manufacturer finds that Attachment 1-1 does not specify the label he needs for a particular system application, the user should contact ARINC for assistance. A page on the IA website has been developed for this purpose:

<http://www.aviation-ia.com/aeec/projects/429/index.html>

2.1.4 Source/Destination Identifier

Bits 9 and 10 of numeric data words are reserved for the Source Destination Identification (SDI). However, these bits are not available for this function in alpha/numeric (i.e., ISO 5) data words or when the resolution needed for numeric (BNR/BCD) data necessitates their use of valid data. The SDI may be used when specific words need to be directed to a specific system of a multi-system installation or when the source system of a multi-system installation needs to be recognizable from the ARINC 429 word content. When the SDI is used, source equipment should encode the aircraft installation number in Bits 9 and 10 as shown in Table 2-1. Sink equipment should recognize words containing its own installation number code and words containing code 00, the all-call code. When the SDI is not used, binary zeros or valid data should be transmitted in Bits 9 and 10.

Table 2-1 – Source/Destination Identifier

Bit Number		Installation Number
10	9	
0	0	all-call
0	1	1
1	0	2
1	1	3

COMMENTARY

Equipment falls into one of three categories: source only, sink only, or both source and sink. Equipment functioning as both a source and a sink should recognize the SDI bits on the inputs and should also encode the SDI bits, as applicable, on the outputs. DME, VOR, ILS, and other sensors are examples of source and sink equipment generally considered to be only source equipment. These are actually sinks for their own control panels. Many other types of equipment are also misconstrued as source only or sink only. A simple rule of thumb is the following: If a unit has an ARINC 429 input port and an ARINC 429 output port, then it is both a source and a sink. With the increase of equipment consolidation, e.g., centralized control panels, the correct use of the SDI bits cannot be overstated.

With regards to all-call, users should be aware that in some installations, the SDI all-call is forfeited and code 00 is used as the installation Number 4 identifier.

This document does not address the practical question of how the SDI bits are set in multi-installation systems. One possible method is to wire program pins on the individual LRU to set the installation code. The ARINC Characteristic devoted to an individual system defines the method actually used.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

2.1.5 Sign/Status Matrix

This section describes the coding of the Sign/Status Matrix (SSM) field. The SSM field uses Bits 30 and 31 in all cases. For BNR data words, the SSM field also includes Bit 29.

The SSM field may be used to report hardware equipment status, such as Normal Operation, Failure Warning, Functional Test, Verified Data, and No Computed Data (NCD).

The following definitions apply:

Invalid Data is defined as any data generated by a source system whose fundamental characteristic is the inability to convey reliable information for the proper performance of a user system. There are two categories of invalid data, namely, No Computed Data and Failure Warning.

No Computed Data is a particular case of data invalidity where the source system is unable to compute reliable data for reasons other than system failure. This inability to compute reliable data is caused exclusively by a definite set of events or conditions whose boundaries are uniquely defined in the system characteristic.

Failure Warning is a particular case of data invalidity where the system monitors have detected one or more failures. These failures are uniquely characterized by boundaries defined in the system characteristic.

The system indicators should always be flagged during a Failure Warning condition.

When a No Computed Data condition exists, the source system should annunciate its outputs to be invalid by setting the sign/status matrix of the affected words to the No Computed Data code, as defined in the subsections which follow. The system indicators may optionally be flagged, depending on system requirements.

While the unit is in the functional test mode, all output data words generated within the unit (i.e., pass through words are excluded) should be coded for Functional Test. Pass through data words are those words received by the unit and retransmitted without alteration.

When the SSM code is used to transmit status and more than one reportable condition exists, the condition with the highest priority should be encoded in Bits 30 and 31. The order of condition priorities to be used is shown in Table 2-2.

Table 2-2 – SSM Condition Priority

Condition	Priority
Failure Warning	1
No Computed Data	2
Functional Test	3
Normal Operation	4

Each data word type has its own unique utilization of the SSM field. These various formats are described in the following subsections.

2.1.5.1 BCD Numeric

When a failure is detected within a system which would cause one or more of the words normally output by that system to be unreliable, the system should stop transmitting the affected word or words on the data bus.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

Some avionic systems are capable of detecting a fault condition which results in less than normal accuracy. In these systems, when a fault of this nature (for instance, partial sensor loss) which results in degraded accuracy is detected, each unreliable BCD digit should be encoded 1111 when transmitted on the data bus. For equipment having a display, the 1111 code should, when received, be recognized as representing an inaccurate digit and a dash or equivalent symbol should be displayed in place of the inaccurate digit. Parameters for which such a degraded mode of operation is possible are identified in the Note column of Attachment 2.

The sign (e.g., plus/minus, north/south, etc.) of BCD Numeric Data should be encoded in Bits 30 and 31 of the word as shown in Table 2-3. Bits 30 and 31 of BCD Numeric Data words should be set to zero where no sign is needed.

The No Computed Data code should be annunciated in the affected BCD Numeric Data word(s) when a source system is unable to compute reliable data for reasons other than system failure.

When the Functional Test code appears in Bits 30 and 31 of an instruction input data word, it should be interpreted as a command to perform a functional test.

COMMENTARY

A typical instruction input to a radio, for example, would be a channel change command word. When this command word is received with the Functional Test coding in the SSM field, the radio should exercise its functional test.

When the Functional Test code appears as a system output, it should be interpreted as advice that the data in the BCD Numeric Data word contents are the result of the execution of a functional test. A functional test should produce indications of 1/8 of positive full-scale values unless indicated otherwise in the associated ARINC Characteristic.

Table 2-3 – BCD Status Matrix

Bit Number		Meaning
31	30	
0	0	Plus, North, East, Right, To, Above
0	1	No Computed Data
1	0	Functional Test
1	1	Minus, South, West, Left, From, Below

2.1.5.2 BNR Numeric Data Words

The status of the transmitter hardware should be encoded in the Status Matrix field (Bits 30 and 31) of BNR Numeric Data words as shown in Table 2-4.

A source system should annunciate any detected failure that causes one or more of the words normally output by that system to be unreliable by setting Bits 30 and 31 in the affected word(s) to the Failure Warning code. Words containing this code should continue to be supplied to the data bus during the failure condition.

The No Computed Data code should be annunciated in the affected BNR Numeric Data word(s) when a source system is unable to compute reliable data for reasons other than system failure.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

When it appears as a system output, the Functional Test code should be interpreted as advice that the data in the word results from the execution of a functional test. A functional test should produce indications of 1/8 of positive full-scale values unless indicated otherwise in the associated ARINC Characteristic.

If, during the execution of a functional test, a source system detects a failure which causes one or more of the words normally output by that system to be unreliable, it should immediately change the states of Bits 30 and 31 in the affected words such that the Functional Test annunciation is replaced with Failure Warning annunciation.

Table 2-4 – BNR Status Matrix

Bit Number		Meaning
31	30	
0	0	Failure Warning
0	1	No Computed Data
1	0	Functional Test
1	1	Normal Operation

The sign (e.g., plus, minus, north, south, etc.) of BNR Numeric Data words should be encoded in the Sign Matrix field (Bit 29) as shown in Table 2-5. Bit 29 should be set to zero when no sign is needed.

Table 2-5 – Sign Matrix

Bit Number		Meaning
29		
0		Plus, North, East, Right, To, Above
1		Minus, South, West, Left, From, Below

Some avionic systems are capable of detecting a fault condition which results in less than normal accuracy. In these systems, when a fault of this nature (for instance, partial sensor loss) which results in degraded accuracy is detected, the equipment should continue to report Normal for the sign status matrix while indicating the degraded performance by coding bit 11 as shown in Table 2-6.

Table 2-6 – Accuracy Status

Bit Number		Meaning
11		
0		Nominal Accuracy
1		Degraded Accuracy

This implies that degraded accuracy can be coded only in BNR words not exceeding 17 bits of data. Parameters for which such a degraded mode of operation is possible are identified in the Notes column of Attachment 2.

2.1.5.3 Discrete Data Words

A source system should annunciate any detected failure that could cause one or more of the words normally output by that system to be unreliable. Three methods are defined. The first method is to set Bits 30 and 31 in the affected word(s) to the Failure Warning code defined in Table 2-7. Words containing the Failure Warning code should continue to be supplied to the data bus during the failure condition.

When using the second method, the equipment may stop transmitting the affected word or words on the data bus. Designers should use this method when the display or use of the discrete data by a system is undesirable. The third method applies to

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

data words which are defined such that they contain failure information within the data field. For these applications, refer to the associated ARINC Characteristic to determine proper SSM reporting. Designers should preclude mixing operational and BITE data in the same word.

The No Computed Data code should be annunciated in the affected Discrete Data word(s) when a source system is unable to compute reliable data for reasons other than system failure.

When the Functional Test code appears as a system output, it should be interpreted as advice that the data in the Discrete Data word contents are the result of the execution of a functional test.

Table 2-7 – Discrete Data Words

Bit Number		Meaning
31	30	
0	0	Verified Data, Normal Operation
0	1	No Computed Data
1	0	Functional Test
1	1	Failure Warning

2.1.6 Data Standards

The units, ranges, resolutions, refresh rates, number of significant bits, pad bits, etc., for the items of information to be transferred by the ARINC 429 bus are tabulated in Attachment 2 to this document.

COMMENTARY

Note that Section 2.3.1.1 of this document calls for numeric data to be encoded in BCD and binary, the latter using two's complement fractional notation. In this notation, the MSB of the data field represents one half of the maximum value chosen for the parameter being defined. Successive bits represent the increments of a binary fraction series. Negative numbers are encoded as the two's complements of positive value and the negative sign is annunciated in the sign/status matrix.

In establishing a given parameter's binary data standards for inclusion in Attachment 2, the units maximum value and resolution are first determined in that order. The Least Significant Bit (LSB) of the word is then given a value equal to the resolution increment, and the number of significant bits is chosen such that the maximum value of the fractional binary series just exceeds the maximum value of the parameter, i.e., equals the next whole binary number greater than the maximum parameter value less one LSB value. For example, to transfer altitude in feet over a range of zero to 100,000 feet, with a resolution of one foot, the number of significant bits is 17, and the maximum value of the fractional binary series is 131,071 (i.e., 131,072 -1).

The resolution provided in an ARINC 429 word should equal or exceed the accuracy of the parameter, so not to degrade it.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

Because data accuracy is a quality of the measurement process and not the data transfer process, accuracy plays no part in the selection of word characteristics.

For the binary representation of angular data, ARINC 429 employs degrees divided by 180° as the unit of data transfer and ± 1 (semi-circle) as the range for two's complement fractional notation encoding (ignoring, for the moment, the subtraction of the LSB value). Thus the angular range 0 through $359.\text{xxx}$ degrees is encoded as 0 through $\pm 179.\text{xxx}$ degrees, the value of the MSB is one half semi-circles and there are no discontinuities in the code.

This is illustrated as follows. Consider encoding the angular range 0° to 360° in 1° increments. Per the general encoding rules above, the positive semi-circle will cover the range 0° to 179° (one LSB less than full range). All the bits of the code are zeros for 0° and ones for 179° , and the sign/status matrix will indicate the positive sign. The negative semi-circle will cover the range 180° to 359° . All bits are set to zero for 180° . The code for angles between 181° to 359° is determined by taking the two's complements of the fractional binary series for the result of subtracting each value from 360 . Thus, the code for 181° is the two's complement of the code for 179° . Throughout the negative semi-circle, which includes 180° , the sign/status matrix contains the negative sign.

For convenience, all binary word ranges in Attachment 2 are shown as whole binary numbers rather than such numbers less one LSB value. Also, the resolutions shown are approximate only. Accurate resolutions can be determined, if required, by reference to the range values and numbers of significant bits for the words of interest.

It should be noted that in all applications of the two's complement fractional notation, the maximum value of the word, once chosen, cannot be changed by the use of more bits in the data field. The number of bits in the word affects only the resolution of the data, not its range.

Binary Coded Decimal (BCD) data is encoded per the numeric subset of the ISO 5 code (see Attachment 5 to this document) using Bits 1 through 4 of the seven-bit-per-character code. Alpha/numeric data is encoded using all seven bits per character of the ISO 5 code and is transmitted using the special word format described in Section 2.3.1.3 of this document.

2.2 Electrically Related Elements

This section describes the digital transfer system elements considered to be principally related to the electrical aspects of the signal circuit.

2.2.1 Transmission System Interconnect

A data source should be connected to the data sink(s) by means of a single twisted and shielded pair of wires. The shields should be grounded at both ends to an aircraft ground close to the rack connector and at all production breaks in the cable.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

COMMENTARY

Cable characteristics and electrical mismatches can produce distortion of the digital data pulses. Likewise, noise due to electrical interference perturbs digital signals.

The performance of a digital receiver will depend upon the receiver input signal characteristics (data with distortion and noise) and the receiver design.

This specification places no restrictions on the number of stubs or length of stubs installed on an aircraft. The voltage and impedance parameters set forth in this document were specified following a thorough analysis of the pulse distortion likely to be encountered in a typical ARINC 429 installation. See Appendix A to this document for a complete report of this investigation.

Tests have shown that some receivers continue decoding data properly when one side of the transmission line is open or shorted to ground. When this condition exists, noise immunity decreases and intermittent operation may occur. Protection against non-annunciated system operation is desired in this mode. This protection may consist of additional circuitry to detect and annunciate the fault or to increase the receiver threshold to above 5.5 Vdc, which is the maximum signal level under this one-wire fault condition.

ARINC 429 receivers should discontinue operation when the voltage thresholds fall into the undefined regions between NULL and HI, or NULL and LO. Manufacturers building ARINC 429 receivers are urged to incorporate this feature in their circuitry.

2.2.2 Modulation

Return-to Zero (RZ) bipolar modulation should be used. This is tri-level state modulation consisting of HI, NULL, and LO states.

2.2.3 Voltage Levels

2.2.3.1 Transmitter Voltage Levels

The differential output signal across the specified output terminals (balanced to ground at the transmitter) should be as shown in Table 2-8 when the transmitter is open circuit.

Table 2-8 – ARINC 429 Voltage Levels

Measurement	State and Voltage (Vdc)		
	HI	NULL	LO
Line A to Line B	+10 ±1.0	0 ±0.5	-10 ±1.0
Line A to Ground	+5 ±0.5	0 ±0.25	-5 ±0.5
Line B to Ground	-5 ±0.5	0 ±0.25	+5 ±0.5

2.2.3.1 Receiver Voltage Levels

The differential voltage presented at the receiver input terminals is dependent upon line length, stub configuration, and the number of receivers connected. In the absence of noise, the normal range of voltage presented to the receiver terminals (Line A to Line B) should be as shown in Table 2-9.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS**Table 2-9 – ARINC 429 Receiver Input**

State	Voltage (Vdc)
HI	+7.25 to +11
NULL	+0.5 to -0.5
LO	-7.25 to -11

In practice, the nominal voltages will be perturbed by noise and pulse distortion. Thus, receivers should associate the following voltage ranges with the three states indicated in Table 2-10.

Table 2-10 – ARINC 429 Receiver Tolerance

State	Voltage (Vdc)
HI	+6.5 to +13
NULL	+2.5 to -2.5
LO	-6.5 to -13

COMMENTARY

Receiver reaction is undefined for voltages that fall in the range just above and below the NULL range. It is desirable that all ARINC 429 receivers discontinue operation when the voltage levels fall into the undefined regions. Manufacturers are urged, as new equipment is developed, to design in the rejection capability.

There is a possibility that transmission lines may encounter conditions that will require receivers to operate with less than the above defined minimum difference of 4.0 Vdc between the NULL and HI, and NULL and LO states. Receiver designers are encouraged to investigate the possibilities and problems of working with a minimum difference of 1 Vdc between these states and to report their findings.

Receiver input common mode voltages (terminal A to ground and terminal B to ground) are not specified because of the difficulties of defining ground with any satisfactory degree of precision. Receiver manufacturers are encouraged to work with the differential input voltage (Line A to Line B) and not line-to-ground voltages.

2.2.4 Impedance Levels**2.2.4.1 Transmitter Output Impedance**

The transmitter output impedance should be 75 ± 5 ohms, divided equally between line A and line B to provide an impedance balanced output. This output impedance should be present for the HI, NULL and LO transmitter output conditions and also during transitions between these levels.

COMMENTARY

The output impedance of the transmitter is specified as 75 ± 5 ohms to provide an approximate match to the characteristic impedance of the cable. The match can only be approximate due to the wide range of characteristic impedances which may be encountered due to the variety of conductor wire gauges and insulation properties.

Measurements on a few samples of wire showed a spread of characteristic impedance of 63 to 71 ohms. An extrapolation over the

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

wire gauges 20 to 26 for wrapped and extruded insulation indicate an expected characteristic impedance spread of 60 to 80 ohms approx. Twisted shielded wire specifications do not control the characteristic impedance of the cable, thus future developments in insulation techniques may result in cables having characteristic impedances outside the range estimated.

2.2.4.2 Receiver Input Impedance

The receiver should exhibit the following characteristics, measured at the receiver input terminals.

Table 2-11 – Receiver Input Impedance

Characteristic	Measurement
Differential Input Resistance	$R_I = 12,000$ ohms minimum
Differential Input Capacitance	$C_I = 50\text{pF}$ maximum
Resistance to Ground	R_H and $R_G \geq 12,000$ ohms
Capacitance to Ground	C_H and $C_G \leq 50\text{pF}$

The total receiver input resistance including the effects of RI, RH, and RG in parallel should be 8,000 ohms minimum (400 ohms minimum for twenty receiver loads).

No more than twenty receivers should be connected on to one data bus, and each receiver should incorporate isolation provisions to ensure that the occurrence of any reasonably probable failure does not cause loss of data to the others.

See Attachment 4 to this document for a description of the input and output circuit standards.

COMMENTARY

The above characteristics apply to differential amplifier receivers. Opto-isolator technology is progressing and may soon find application in digital data receivers. Opto-isolator receivers impose slightly greater loads on data buses than differential amplifier receivers and the way in which they are characterized is different.

2.2.5 Fault Tolerance

2.2.5.1 Receiver External Fault Voltage Tolerance

Receivers should withstand without sustaining damage the following steady-state voltages being applied to their terminals, superimposed upon a normally operating bus. Operation within specification limits is not required under these conditions.

- a. 30 Vac RMS applied across terminals A and B, or
- b. ± 29 Vdc applied between terminal A and ground, or
- c. ± 29 Vdc applied between terminal B and ground.

2.2.5.2 Transmitter External Fault Voltage

Transmitter failures caused by external fault voltages should not cause other transmitters or other circuitry in the unit to function outside of their specification limits or to fail.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

2.2.5.3 Transmitter External Fault Load Tolerance

Transmitters should indefinitely withstand without sustaining damage a short circuit applied:

- Across terminals A and B, or
- From terminal A to ground, or
- From terminal B to ground, or
- Items b and c above, simultaneously.

2.2.6 Fault Isolation

2.2.6.1 Receiver Fault Isolation

Each receiver should incorporate isolation provisions to ensure that the occurrence of any reasonably probable ARINC 429 bus receiver failure does not cause any input bus to operate outside of its specification limits (either under-voltage or over-voltage).

2.2.6.2 Transmitter Fault Isolation

Each transmitter should incorporate isolation provisions to ensure that it does not, under any reasonably probable LRU fault condition, provide an output voltage in excess of:

- 30 Vac RMS between terminal A and B, or
- ± 29 Vdc between A and ground, or
- ± 29 Vdc between B and ground.

2.3 Logic Related Elements

This section describes the digital transfer system elements considered to be principally related to the logic aspects of the signal circuit.

2.3.1 Digital Language

2.3.1.1 Numeric Data

An ARINC 429 bus should accommodate numeric data encoded in two digital languages, BNR expressed in two's complement fractional notation and BCD per the numerical subset of ISO 5 (see Attachment 5 to this document). An information item encoded in both languages is assigned a unique address for each (see Section 2.1.3 and Attachment 1-1). Word formats are shown in Attachment 6 to this document.

2.3.1.2 Discretes

In addition to handling numeric data as specified above, the ARINC 429 bus should also be capable of accommodating discrete items of information either in the unused (pad) bits of data words or, when necessary, in dedicated words. Any discrete information contained in a numeric data word assigned a label in Attachment 1-1 is specified in the definition for that word in Attachment 6.

The rule to be followed in the assignment of soft bits to discrete in numeric data words is to start with the LSB of the word and to continue towards the MSB available in the word. Attachment 6 shows the generalized word structure.

There are two types of discrete words. These are general purpose discrete words, and dedicated discrete words. Seven labels (270 to 276) are assigned to the

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

general purpose words in Attachment 1-1. These words should be used in ascending label order (starting with 270) when the system receiving the data can identify its source by reference to the port at which it arrives.

2.3.1.3 Maintenance Data (General Purpose)

The general purpose maintenance words are assigned labels in sequential order as are the labels for the general purpose discrete words. The lowest octal value label assigned to the maintenance words should be used when only one maintenance word is transmitted. When more than one word is transmitted the lowest octal value label should be used first and the other labels used sequentially until the message has been completed. The general purpose maintenance words may contain discrete, BCD, or BNR numeric data but should never contain ISO 5 coded messages. The general purpose maintenance words should be formatted according to the layouts of the corresponding BCD/BNR/discrete data words shown in Attachment 2.

2.3.1.4 AIM Data

The original contents of this section have been moved to Part 3 of ARINC Specification 429. For reference purposes, the section header is retained.

2.3.1.5 File Data Transfer

The bit-oriented protocol is defined in Part 3 of ARINC Specification 429 and is preferred for new applications. The purpose of bit-oriented communication is to enable the transparent transfer of data.

COMMENTARY

The data transparent protocol described in Part 3 was developed to facilitate ACARS Management Unit (MU) and the Satellite Data Unit (SDU) communications. The viability as a universal protocol was recognized by the Systems Architecture and Interfaces (SAI) Subcommittee, which recommended its inclusion herein as the standard means of file data transfer.

The process for determining what protocol (character-oriented or bit-oriented) should be used in the interaction between two units, where this information is not pre-determined, is described in Part 3 of ARINC 429.

2.3.1.5.1 Bit-Oriented Protocol Determination

The ALO word (for Aloha) should be sent by any system which supports the bit-oriented Link Layer protocol just after the system powers-up or performs a re-initialization for any reason. The Aloha response is in the ALR word. The ALO/ALR protocol process may also be used when a bit-oriented Link Layer protocol system needs to determine if any of its interfaces support the bit-oriented protocol. All systems that support the Link Layer bit-oriented protocol must be able to respond to the initiation of this process. Attachment 11C of Part 3 of ARINC Specification 429 shows the ALO and ALR word formats.

When a system with a bit-oriented Link Layer protocol has the need to make this determination, it should construct the ALO word and transmit this word to the device in question. The system should then wait for a maximum period of time defined by T_{12} . If the device in question has not responded within T_{12} , the initiating system

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

should initiate another ALO word and again delay up to T_{12} . An initiating system should attempt a maximum of N_6 ALO word operations before declaring the device in question as not bit-oriented or not able to respond.

2.3.2 Transmission Order

The Least Significant Bit (LSB) and the least significant character of each word should be transmitted first. Note that the LSB of the word is the Most Significant Bit (MSB) of the label, and the label is transmitted ahead of the data in each case. This reversed label characteristic is a legacy from past systems in which the octal coding of the label field was, apparently, of no significance.

2.3.3 Data Bit Encoding Logic

A HI state after the beginning of the bit interval returning to a NULL state before the end of the same bit interval signifies a logic one.

A LO state after the beginning of the bit interval returning to a NULL state before the end of the same bit interval signifies a logic zero. This is represented graphically in Attachment 7 to this document.

2.3.4 Error Detection/Correction

The last bit of each word (Bit 32) should be encoded such that word parity is rendered odd to allow error detection in receivers. Note that the parity calculation encompasses all 31 bits assigned to label and information within a word.

COMMENTARY

Industry experience with digital information transfer systems has shown that a twisted shielded pair of wires can be regarded as a high integrity link, and unlikely to introduce bit errors into the data passing through it. For this reason, no means of error correction are specified for ARINC 429. The error detection capability specified above may be used as desired in receiving terminals. BNR data, for example, may be checked for parity by reference to the binary state of Bit 32 of each word. Also, the data may be submitted to reasonableness checks. BCD data intended for human consumption in the cockpit is normally smoothed before transmission to ensure tolerable levels of display jitter. As this process eliminates any wild data points, the need for further error detection is questionable. As pointed out in the Commentary following Section 2.1.2 of this document, the parity bit was added to the BCD word for reasons related to BCD/BNR transmitter hardware commonality, not because a need for it existed for error detection.

2.4 Timing Related Elements

This section describes the digital data transfer system elements considered to be principally related to the timing aspects of ARINC 429.

2.4.1 Bit Rate

2.4.1.1 High-Speed Operation

The bit rate for ARINC 429 high-speed operation is 100 kilobits per second (100 kbps) $\pm 1\%$.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS**2.4.1.2 Low-Speed Operation**

The bit rate for ARINC 429 low-speed operation should be within the range of 12.0 kbps to 14.5 kbps. The selected rate should be maintained within $\pm 1\%$.

Note: High bit rate and low bit rate messages will not be intermixed on the same bus.

COMMENTARY

Although the bit rates specified above should be held within the stated tolerances over the long term, individual bit lengths may fall outside the limits expected from these tolerances. Bit symmetry and jitter should be within the tolerances specified in Attachment 8.

Also, notwithstanding the RFI performance described in Appendix 1 of this document, system designers are advised to avoid selection of 13.6 kbps for low-speed operations and precisely 100 kbps for high-speed operations to ensure that the system is not responsible for interference to avionics systems.

2.4.2 Information Rates

The minimum and maximum transmit intervals for each item of information transferred by ARINC 429 are specified in Attachment 2. Words with like labels but with different SDI codes should be treated as unique items of information. Each and every unique item of information should be transmitted once during an interval bounded in length by the minimum and maximum values specified in Attachment 2. Stated another way, a word having the same label and four different SDI codes should appear on the bus four times (once for each SDI code) during that time interval.

COMMENTARY

There are no values given for refresh rates in this specification. However, it is desirable that data be refreshed at least once per transmission. Those data actually requiring long processing times or a large number of samples are the only types not expected to be refreshed with every transmission.

Discretes contained within data words should be transferred at the bit rate and repeated at the update rate of the primary data. Words dedicated to discrete data should be repeated continuously at the rates defined in Attachment 2.

COMMENTARY

The time intervals between successive transmissions of a given BCD word specified in Attachment 2 to this document are, in general, too short for the signal to be of use in driving a display device directly. For example, the display would change too rapidly for human perception. Thus, display designers should incorporate into their devices means for selecting those words to be used for updating the display from the greater quantity delivered.

2.0 DIGITAL INFORMATION TRANSFER SYSTEM STANDARDS

2.4.3 Clocking Method

Clocking is inherent in the data transmission. The identification of the bit interval is related to the initiation of either a HI or LO state from a previous NULL state in a bipolar RZ code.

2.4.4 Word Synchronization

The digital word should be synchronized by reference to a gap of four bit times (minimum) between the periods of word transmissions. The beginning of the first transmitted bit following this gap signifies the beginning of the new word.

2.4.5 Timing Tolerances

The waveform timing tolerances should be as shown in Attachment 8 to this document. It is important that the RF interference radiated and conducted by an ARINC 429 bus does not exceed that permitted by **RTCA Document DO-160: Environmental Conditions and Test Procedures for Airborne Equipment**. Appendix 1 to this document provides additional detail.

3.0 APPLICATIONS NOTES

3.0 APPLICATIONS NOTES

3.1 Radio Systems Management

One special application of the ARINC 429 data bus is radio systems frequency selection and switching. The following sections set forth the rules which should be followed in the application of ARINC 429 to ensure interoperability of radios and control sources.

3.1.1 Word Format and Digital Language

The standard 32-bit BCD word should be used, of which Bits 1 through 8 constitute the label. Bits 9 and 10 are reserved for a Source/Destination Identifier (SDI) code. Bits 11 through 29 constitute the data field. Bits 30 and 31 form the Sign/Status Matrix (SSM). Bit 32 is the word parity bit.

The label defines what radio to be tuned. The data field contains the frequency to which the radio should be tuned, as encoded in BCD characters, together with the discretes required for function switching for that radio. Attachment 6 to this document shows how the word should be structured for each radio system.

3.1.2 Update Rate

The nominal update rate for all radio systems management words should be five times per second.

3.1.3 Sign/Status Matrix (SSM)

The normal state of the SSM is binary zeros. However, the radios should recognize the codes for Functional Test and No Computed Data (see Section 2.1.5 of this document). Radios should interpret the former as an instruction to perform a Functional Test or functional test sequence. They should regard the latter as an instruction to remain tuned to the frequency contained in the last valid word received until either another valid word is decoded or their primary power is removed.

3.1.4 Frequency Ranges and Switching Functions

3.1.4.1 Automatic Direction Finder (ADF)

Frequency Range	190kHz to 1750kHz
Frequency Selection Increment	0.5kHz
Characters encoded in ARINC 429 word	1000kHz, 100kHz, 10kHz, 1kHz
Switching Functions	0.5kHz on/off, BFO on/off, ADF/ANT mode selection

3.1.4.2 Distance Measurement Equipment (DME)

Frequency Range (VOR/ILS)	108.00MHz to 135.95MHz
Frequency Selection Increment: (VOR/ILS)	50kHz
Characters encoded in ARINC 429 word	10MHz, 1MHz, 0.1MHz 0.05MHz (VOR/ILS only) 100MHz character is 1 for VOR/ILS 10MHz character is limited to 7
Switching Functions	VOR/ILS/MLS Frequency, DME modes, Directed Frequency Numbers, Display Control

3.0 APPLICATIONS NOTES**3.1.4.3 High-Frequency (HF) Communications**

Frequency Range	2.8MHz to 24MHz
Frequency Selection Increment	1kHz or 0.1kHz
Characters encoded in ARINC 429 words	10MHz, 1MHz, 0.1MHz
Switching Functions	USB/LSB mode selection SB/AM mode selection

Note: Two words may be transmitted for HF frequency selection to facilitate frequency resolution of 0.1kHz.

3.1.4.4 Instrument Landing System (ILS)

Frequency Range	108.00MHz to 111.95MHz
Frequency Selection Increment	50kHz
Characters encoded in ARINC 429 words	10MHz, 1MHz, 0.1MHz, 0.01MHz (100MHz character is always decimal 1)
Switching Functions	None

3.1.4.5 VOR/ILS

Frequency Range	108.00 MHz to 117.95MHz
Frequency Selection Increment	50kHz
Characters encoded in ARINC 429 words	10MHz, 1MHz, 0.1MHz, 0.01MHz (100MHz character is always decimal 1)
Switching Functions	ILS Mode

3.1.4.6 VHF Communications

Frequency Range	117.975MHz to 137.000MHz
Frequency Selection Increment	25kHz or 8.33kHz
Characters encoded in ARINC 429 words	10MHz, 1MHz, 0.1MHz, 0.01MHz (100MHz character is always decimal 1)
Switching Functions	None

3.1.4.7 Air Traffic Control (ATC) Transponder

The ATC Transponder operates on two frequencies (one receive and one transmit) which do not require selection. Reply code selection, however, is required, and ARINC 429 supports this selection.

Reply Code Ranges	0-7 in four independent groups
Code increments	1 decimal digit per group
Characters encoded in ARINC 429 words	ALL
Switching Functions	Ident. Pulse Select, Altitude Reporting On/Off, Altitude Source Select, X-pulse Select (reserved), VFR/IFR Select (reserved), IRS/FMC Input Select (reserved)

	XXX	1	1	1	1	1	1	1	1	Equipment Identification			X	6-17>Note 2	

Notes:

1. XXX or YYY is applicable to all Equipment IDs.
2. The preferred SSM encoding method for the Equipment Identification Word is according to the Discrete word guidelines. When this label was originally assigned, it was recognized as a non-BNR word. The SSM encoding was according to the BCD and DISC guidelines that were identical at that time. During development of Supplement 4, the SSM for DISC was revised to its current form to provide enhanced failure warning. When the SSM encoding was changed, some systems retained the BCD encoding for the Equipment Identification word and others changed to DISC encoding. There are ARINC standards that are still active that have the SSM for Equipment Identification designated as BCD. You will need to check with the equipment manufacturer to determine the SSM format.
3. The Label does not adhere to ARINC 429 Standard Signal Format and contains both BCD and BNR bit encoding depending on the selected mode.

Notes:

- The number entered into the Range Column for each parameter that is not angular in nature is the nearest whole binary number greater than the parameter range required. As explained in the Commentary following Section 2.1.6 of this document, the weight of the most significant bit of the two's complement fractional notation binary word will be one half this value, and the actual maximum value of the parameter capable of being encoded will be the number in the range column less one least significant bit value. The numbers entered in the RANGE column for angular parameters are the actual degree ranges required. The way in which these parameters are encoded is also explained in the Commentary following Section 2.1.6.
- Transmit intervals and the number of parameters to be transmitted are prime factors in bus loading. The interval for transmission of parameters should fall between the minimum and maximum specified intervals and nominally should be near the center of the range at equal intervals between transmissions. When heavy bus loading dictates a shift from the center of the range, the shift should be toward the maximum transmit interval.

**ATTACHMENT 2B
DATA STANDARDS - BNR DATA**

When words with like labels and with different SDI codes are transmitted, each of those words is considered a unique item of information. The guidance given in this document for transmit intervals should be applied to those words as if each word were identified by a different label.

- 3 Maximum transport delay is the worst case total delay between an input function and the output response.

COMMENTARY

Since the nature of the data varies, the definition of transport delay will differ depending on the application. In the case of a sampling system, a sample is complete when the 32-bit word constituting the output data is complete. In the case of a system involving filtering, transport delay is the phase slope of the transfer function across the frequency band of interest.

There can be situations in which it is necessary to define which portions of an equipment are included in the transport delay term. Such definitions should appear in individual equipment Characteristics when needed.

- 4 The values shown in parentheses are the preferred data standards for stator vane angle. However, a considerable portion of existing equipment use the other (non-parenthesized) values. Users should verify the data standards of the equipment they are or will be using.
- 5 These labels can provide data in a degraded accuracy mode. See Section 2.1.5.1 and 2.1.5.2.
- 6 Optionally transmitted.
- 7 Binary packed word consisting of:

Word 1 = Bits 11-19 (Range = 16)
Word 2 = Bits 20-28 (Range = 16)

**ATTACHMENT 3
VOLTAGE LEVELS**

ATTACHMENT 4
INPUT/OUTPUT CIRCUIT STANDARDS

OUTPUT (SYSTEM) CAPABILITY

Total System *Resistance	400 to 8,000 ohms
Total System *Capacitance	1,000 to 30,000 pF
System Capacitance Unbalance	Not defined but unbalance due to aircraft interwiring should be held to a minimum

UTILIZATION DEVICE STANDARDS

$R_I \geq 12,000$ ohms
$C_I \leq 50$ pF
R_H or $R_G \geq 12,000$ ohms
C_H and $C_G \leq 50$ pF

The total differential input impedance of the receiver should be limited to the values specified in Section 2.2.4.2.

This drawing describes total system characteristics rather than individual component parameters.

Notes::

* Includes aircraft interwiring

** Shields to be grounded in aircraft at both ends of all "breaks."

Documentary Data Word[1] Source/Destination Identifier (SDI) Field

The purpose of the SDI field is explained in Section 2.1.4 of this document, as are also the limitations on its use. When the SDI function is not required, this field may be occupied by binary zero or valid data pad bits.

[2] Discretes

As discussed in Section 2.3.1.2 of this document, unused bits in a word may be assigned to discrete functions, one bit per variable. Bit #11 of the word should be the first to be so assigned, followed by bit #12 and so on, in ascending numerical order, until the data field is reached. In the absence of discretes, unused bit positions should be occupied by binary zero or valid data pad bits.

[3] Pad

All bit positions not used for data or discrete should be filled with binary zero or valid data pad bits. Section 2.1.2 of this document refers.

[4] Sign/Status Matrix (SSM)

Section 2.1.5 of this document describes the functions of the sign/status matrix and the ways in which the bits constituting it are encoded.

[5] Parity Bit

This bit is encoded to render word parity odd. Section 2.3.4 of this document refers.

NOTES:

- [1] "P" denotes pad "zero" or valid data, see Section 2.1.2. Note possible use of pad bits for discrete functions per Section 2.3.1.2.
- [2] Because of the actual maximum value of the most significant character of these quantities exceeds 7, it cannot be encoded in the most significant character position of the BCD word. For this reason, each quantity has been given an "artificial" MSC of zero and its actual MSC encoded in the next most significant character position of the word.

NOTES:

- [1] “P” denotes pad “zero” or valid data, see Section 2.1.2. Note possible use of pad bits for discrete functions per Section 2.3.1.2.
- [2] Negative values are encoded as the two’s complements of positive values and the negative sign is annunciated in the sign/status matrix.
- [3] Angles in the range 0 to 180° are encoded as positive numbers. Angles in the range 180° to 360° are subtracted from 360° and the resulting number encoded as a negative value per note 2. Arc minutes and seconds are encoded as decimal degrees.

Label 236 EO ID 018

NOTE: The following information is provided in order to clarify the confusion that existed in the Industry in regards to definition of the SSM for Label 233-236. It is expected that Flight ID will be sourced from FMC EQ ID of 002. Alternative implementation may include Mode "S" XPDR EQ ID 018. In this case the user cautioned that the SSM will be BCD format. See ARINC Characteristic 718A, "Mark 4 Air Traffic Control Transponder (ATCRB/MODE S)", Attachment 3A for more detailed information.

ATTACHMENT 6
GENERAL WORD FORMATS AND ENCODING EXAMPLE

TABLE 6-35
FQIS System Data - Label 241 04D

LABEL:	241
EQPT ID:	04D
PARAMETER NAME:	FQIS System Data
UNITS:	(See Below)
RANGE (SCALE):	(See Below)
SIGNIFICANT DIGITS:	(See Below)
RESOLUTION:	(See Below)
MIN TRANS INTERVAL (msec):	500
MAX TRANS INTERVAL (msec):	1024
SOURCE DESTINATION IDENTIFIER:	01 – LEFT MAIN TANK 10 – RIGHT MAIN TANK 11 – CENTER TANK

Label 241 is transmitted approximately once per second. The data encoding depends on the sequence which it is transmitted. Label 241 transmitting sequence, as defined below, starts with the left main tank data followed by the right main tank and then the center tank. Once all the tank data has been transmitted (63 words of data), the sequence will repeat with word number 1, left main tank, and so on. To determine the data that is transmitted at any specific time requires knowing where in the following sequence the word is taken.

LABEL 241 WORD SEQUENCE

Word	Signal	Units	Range	Sig. Dig.	Res	Data
1	LEFT MAIN TANK NO. 1	pF	319.922	12	.078125	BNR

TABLE 6-41

DME		PARITY (odd)	SIGN/STATUS MATRIX	10 MHz	1 MHz	0.1 MHz	0.00/0.05 MHz	IDENT DISPLAY	MLS FREQ.	ILS FREQ.	DME Mode	SDI	LABEL DME Frequency (035)		
Function	Bit No.	Example	Notes [1] [5]	29 28 27 0 0 1	26 25 24 23 0 1 0 1	22 21 20 19 0 1 1 0	18 1 [2]	17 16 0 1 [7]	15 0 [3]	14 0 [4]	13 12 11 0 0 0	10 9 0 0	8 7 6 1 0 1	5 4 3 1 1 0	2 1 0 0 0 0
Bit No. Example	32 1	31 30 0 0													

- [1] Directed Frequency #1, 115.65 MHz, VOR
- [2] Bit 18 is used only for VOR & ILS frequencies and is limited to .00 or .05
- [3] Bits 15 & 14 codes: VOR (0,0), ILS (0,1) or MLS (1,0), (1,1) is spare
- [4] Refer to table in Section 4.1.2 of ARINC Characteristic 709 for mode codes
- [5] Although not encoded in the tuning word all VOR & ILS frequencies have 1 as hundreds digit. Although not encoded in the tuning word all MLS frequencies have 5 as the thousand digit and 0 as the hundred digit. Add 5031 MHz to the coded value to obtain the MLS frequency.
- [6] (Original note deleted)
- [7] Bit 16 when equal to “one” specifies that a displayable BCD output is to be provided for that station, and when bit 17 is a “one,” an ident output is to be generated for that station.

Horizontal Alarm Limit/Horizontal Integrity Threshold (BNR) – Label 124 – IE2

32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8 7 6	5 4 3	2 1				
P	SSM [Note 1]		Horizontal Alarm Limit (HAL) /Horizontal Integrity Threshold [Notes 2, 3]													Pad [Note 4]	Phase of Flight [Note 5]		Octal Label											
																4	2		1											
																0 0 1	0 1 0		1 0											

[1] SSM (Status Matrix):

BITS		Meaning
31	30	
0	0	Failure Warning
0	1	No Computed Data (NCD)
1	0	Functional Test
1	1	Normal Operation

[2] Horizontal Alarm Limit (HAL) / Horizontal Integrity Threshold

The LDPU's optional internal GNSS receiver will generate a horizontal position integrity alarm when the EPU (Estimated Position Uncertainty) exceeds the Horizontal Alarm Limit for a period of time equal to the Time To Alarm for the current phase of flight. If the value of the HPL (Horizontal Protection Level, label 130) output from the internal GNSS receiver exceeds the horizontal integrity threshold specified in label 124, then horizontal integrity is deemed to be unavailable.

In the HAL field, the LSB (bit 16) has a weight of 1 meter, while the MSB (bit 28) has a weight of 4096 m.

[3] “All Ones” Value for HAL Field

If an “all ones” value is encoded into bits 28 to 18, the HAL value should be assumed to be the default value for the phase of flight specified in bits 13 to 11. If the HAL value is “all ones” (8191 meters) and the phase of flight code is “000” (“unspecified”) then the SSM field should be set to NCD.

[4] Pad Bits

The pad bits, bits 15 and 14, should be set to 0.

[5] Phase of Flight

The “phase of flight” field, bits 13 to 11, informs an optional GNSS receiver within the LDPU of the current phase of flight, so that the GNSS receiver may adjust its internal parameters to meet requirements for that phase of flight.

BITS			Phase of Flight	Alarm Limit		Time To Alarm
13	12	11		Horizontal	Vertical	
0	0	0	Not Specified	Unchanged	Unchanged	Unchanged
0	0	1	Oceanic	4 NM (7408 m)	N/A	8 s
0	1	0	En Route	2 NM (3704 m)	N/A	8 s

																							7	2	1						
																							1	1	1	0	1	0	1	0	

[1] SSM (Status Matrix):

BITS		Meaning
31	30	
0	0	Failure Warning
0	1	No Computed Data
1	0	Functional Test
1	1	Normal Operation

[2] Vertical Alarm Limit (VAL) / Vertical Integrity Threshold

The LDPU's optional internal GNSS receiver will generate a vertical position integrity alarm when the estimated error in vertical position exceeds the Vertical Alarm Limit for longer than the time-to-alarm for the current phase of flight. (The phase of flight is specified in label 124.) If the value of the VPL (Vertical Protection Level, label 130) output from the internal GNSS receiver exceeds the vertical alarm limit specified in bits 28-21, then vertical position integrity is defined to be "unavailable."

The LSB, bit 21, has a weight of 1 meter, while the MSB, bit 28, has a weight of 128 m.

[3] Pad Bits

The pad bits, bits 20 to 11, should be set to 0.

APPENDIX A
LABORATORY VERIFICATION OF ARINC 429 ELECTRICAL CHARACTERISTICS

A1-1.0 Introduction

Selection of the electrical characteristics of the ARINC 429 followed verification of the suitability of proposed values in laboratory tests performed by the Boeing Commercial Airplane Co. Boeing presented two reports to AEEC's Systems Architecture and Interfaces Subcommittee on these activities, one at the meeting held in Arlington, Virginia, in March 1977 and the other at the meeting held in Los Angeles, California, in May 1977. The material in this Appendix is excerpted from these reports.

A1-2.0 Electromagnetic Emission and Susceptibility Tests

Electromagnetic emission and susceptibility tests were conducted to determine if the proposed 100 kbps waveform was suitable for use in a commercial airplane EMI environment. The EMI conditions used for the tests were derived from RTCA Document DO-160, "Environmental Conditions and Test Procedures for Airborne Electronic/Electrical Equipment and Instruments" dated February 28th, 1975.

A1-2.1 Cable and Test Configuration

The cable used for the tests was standard aircraft type twisted shielded wire of 22 AWG. The wire configuration consisted of approximately 60 ft. of cable which was subjected to the EMI environment within a screened room. This cable was connected in series with 300 ft. of cable not subjected to the EMI environment. The test was configured to simulate the maximum length wire run with DO-160 conditions applied.

The 60 Ft. length of cable was connected to the transmitter for the emission tests and to the receiver for the susceptibility tests.

A1-2.2 Transmitter Characteristics

The block schematic of the bipolar line driving transmitter built for the tests is shown in Figure a-(i). The waveform was shaped at the pulse generator such that it exhibited the following characteristics:

Differential Output Voltage:	
HI	+10V
NULL	0V
LO	-10V
Risetime = Falltime = 1.0 μ sec	
Bit Rate= 100 kilobits/second	
HI time= NULL time= LO time	

A1-2.3 Receiver Input Circuit Description

To perform the susceptibility tests, receivers were constructed utilizing various methods of common mode rejection and various processing schemes.

Differential Amplifier Input. Figure a-(ii) shows schematics of the differential input stages used for the receivers. The differential amplifier input stage required resistors to local ground at the input to provide a path for the input current for the voltage followers. Voltage protection was used to prevent damage to the voltage followers in the event of high voltage, common mode spikes. The voltage follower stages provided a controlled impedance for the differential amplifier stage.

Opto-Isolator Input The opto-isolator input stage utilized two H-P 5082-4371 isolators connected in opposite polarity to detect the bipolar data. The HP 5082-4371 input has a forward conduction "knee" at approximately 1.4 volts. A second simple LED (HP 5082-4650) was connected in series with each opto-isolator to provide a combined knee voltage of approximately 3 volts. A series resistor RL of 1000 ohms was placed in series with the LED/opto-isolator network to limit the receiver current to 7mA at 10 volts (differential) applied at the input. At 4.5V differential on the line, one opto-isolator conducts 1.5 mA.

One circuit configuration which enables the opto-isolator to operate at 100 kilobits per second at these low input currents is shown in figure a-(iii). A potential of +15 volts is applied to pin 8 to provide maximum gain in the first transistor. During conduction, a charge on the second transistor is discharged via pin 7 and R2 to a potential of +0.5 volts set by R1 and R3. Discharging to a +0.5 volt potential reduces the possibility of a loss of the first bit following a long null period. This problem has been observed when discharging pin 7 to ground potential.

APPENDIX A
LABORATORY VERIFICATION OF ARINC 429 ELECTRICAL CHARACTERISTICS

A1-2.4 Receiver Data Detection Technique

Two data detection schemes were used, (i) data sampling (sample and decision) and (ii) integrate and dump (Figure a-(iv)).

The data sampling system detects positive-going or negative-going edges which exceed ± 3 volts differential voltage. The edges cause a timing circuit to time for approximately 2 μ sec. When the timing circuit has timed out, a sample of the input is taken. If the sample is HI, a ONE is declared. If the sample is LO, a ZERO is declared. If the sample is NULL, an error diagnostic can be output, since a NULL state is known to be invalid at the data sampling time. An error diagnostic will be output if, for example, during a period of NULL on the line, a short-duration noise spike causes the input to exceed the $\pm 3V$ threshold, so initiating the edge detector timing circuit, but dissipates rapidly so that a NULL is estimated at the data sampling time.

The integrate-and-dump processor circuit detects positive or negative-going edges which exceed the $\pm 3V$ differential threshold. The edge detection causes an integration circuit to integrate the input voltage for a period of 5 μ sec. The output of the integrator is sampled (timing is derived from the edge detector) at the end of the integration period. If it is above zero voltage, a ONE is declared; if it is below zero voltage, a ZERO is declared.

A threshold level could be introduced about zero voltage to provide an indication of the total energy contained in the pulse. If the integrator output fell within the threshold, an error diagnostic could be presented indicating the at the detection of the bit was marginal.

A1-2.5 Test Data Message

The test waveform was a continuous pseudo-random bit pattern. This continuous pattern did not test the initial synchronization or "false-alarm" aspects in a word-by-word transmission environment with NULL on the transmission line between words.

A1-2.6 Emission of RF Energy Test Results

The following tests were performed under conditions of light (one receiver) and heavy (20 receivers) line loading.

- A. Conducted RF Interference (RTCA DO-160 Paragraph 21.2)
The interference measured was within the limits specified in DO-160 Figure 21-2.
- B. Radiated RF Interference (RTCA DO-160 Paragraph 21.3)
The interference measured was within the limits specified in DO-160 Figure 21-5.

It should be noted that the 20dB limit exceedance permitted in DO-160 was not taken. The transmitter output spectrum can be further improved by the addition of filtering to attenuate output frequencies above those of interest in the digital data.

A1-2.7 Susceptibility Test Results

The tests were performed to determine the susceptibility of the ARINC 429 to RF, AF and spike interference levels specified in DO-160 under conditions of light (one receiver) and heavy (20 receivers) line loading.

The following receiver configurations were tested:

- (i) Differential Amplifier input, time sample processing
- (ii) Differential Amplifier input, integrate-and-dump processing
- (iii) Opto-isolator input, time sample processing
- (iv) Opto-isolator input, integrate-and-dump processing

The data transmitted consisted of a continuous pseudo-random bit sequence. Error checking was made on a bit-by-bit basis.

- A. Conducted RF Susceptibility (DO-160 Paragraph 20.20B Category Z)
No bit errors were detected with RF applied to any of the line loading and receiver configurations.
- B. Magnetic Fields Induced Into Interconnecting Cables (DO-160 Paragraph 19.3)
Test performed at a level above those specified in DO-160 Figure 19-1. No bit errors were detected with the field applied to the cable for any cable loading or receiver configuration.

APPENDIX A
LABORATORY VERIFICATION OF ARINC 429 ELECTRICAL CHARACTERISTICS

- C. **Electric Fields Induced Into Interconnecting Cables** (DO-160 Paragraph 19.4)
The tests were performed with voltage levels above those specified in DO-160 Figure 19-1 Category Z. No bit errors were detected with the field applied for any cable loading or receiver configuration.
- D. **Spikes Induced Into Interconnecting Cables** (DO-160 Paragraph 19.5, Category Z)
The spikes were generated and applied to the cable as shown in DO-160, Figure 19-4. Bit errors were counted during the application of 50 transients and also following the transient test. The following results were observed:

Receiver Configuration	Line Light	Loading Heavy
Diff. Amp., Sample Det	0	0
Diff. Amp., Int. & Dump Det	0	0
Opto-Isolator, Sample Det	8	15
Opto-Isolator, Int & Dump Det	0	1

All configurations performed with zero bit errors for approximately 10^7 bits following the transient test.

A1-3.0 Pulse Distortion Tests For Typical Aircraft wire Installations

Laboratory testing and computer simulation studies were conducted to investigate the pulse distortion introduced on typical aircraft wire installations.

A1-3.1 Laboratory Tests

Receivers and a transmitter were constructed to operate using the ARINC 429 high-speed (100 kbps) waveform. Lengths of twisted shielded cable were connected to form a representative wiring configuration for digital data. The wire length and stub configuration were selected to represent postulated installations on a B747 airplane. The cable used for lab tests was 20 and 22 AWG twisted shielded cable with wrapped KAPTON insulation, no. BMS B-51, Class 2 type III. The pulse distortions at the receiver nodes of the wiring systems were recorded. The characteristics of the 20 AWG cable were measured and used to develop the cable model used in the computer simulation.

A1-3.2 Computer Simulation

A computer program was developed to evaluate pulse distortion on lines with stubs. The ARINC 429 transmitter impedance and voltage waveform was modeled. The cable model was developed from the measured cable characteristics. The ARINC 429 receiver input impedance was modeled.

The computer simulation was run and results were plotted for various line length and stub configurations representing postulated installations on a B747 airplane.

A1-3.3 Results

The results of the laboratory tests and computer simulation for the same cable configuration showed good agreement, with a maximum difference of 0.4 volts on rising and falling edges. The computer simulation showed slightly higher cable loss effect than the lab test. The lab test results were recorded using an oscilloscope camera; the computer results were plotted. Only the plotted results are presented here.

Figure a-(v) shows the schematic for the first simulation. This configuration represents a transmitter, a receiver and a single length of twisted shielded cable 200 feet long. The cable is modeled as Blocks 1 to 4, for later stub connection.

At the transmitter and receive ends of the cable, the shields are grounded via a 0.05 μ H inductor (which models the inductance of the ground lead). At other nodes, the shields and cable innards are carded through, representing a continuous length of cable.

Figure a-(vi) Transmitter open circuit differential output voltage. This waveform was used for all the simulation runs.

Figure a-(vii) The transmitter output voltage and receiver input voltage for the configuration in Figure a-(v).

Figure a-(viii) shows the schematic for the second simulation. This configuration represents a transmitter at an engine location, with receivers at the equipment bay and the flight deck. Four receiver loading configurations are shown with maximum loading of twenty receivers. The waveforms for this simulation run are shown in Figures a-(ix) through a-(xvi).

**APPENDIX A
LABORATORY VERIFICATION OF ARINC 429 ELECTRICAL CHARACTERISTICS**

Figures a-(ix) and a-(x) Transmitter and receiver waveform for loading configuration 1.

Figures a-(xi) to a-(xvi) Waveforms for loading configurations 2, 3 and 4.

Figure a-(xvii) shows the schematic for the third simulation. This configuration represents a transmitter at the flight deck with receivers at the equipment bay, the inner engine and the outer engine.

Figures a-(xviii) to a-(xxi) Waveforms for the third simulation.

Figure a-(xxii) shows the schematic for the fourth simulation. This configuration represents a transmitter at the equipment bay with receivers at the equipment bay, the flight engineer's panel, the first officer's panel and the captain's panel.

Figures a-(xxiii) to a-(xxvi) Waveforms for the fourth simulation.

Figure a-(xxvii) shows the schematic for the fifth simulation. This is a long line simulation and is included to show the operation of the system with lines longer than would realistically be used in a B747-sized airplane. This configuration represents a transmitter with one receiver close (10 feet) and one receiver remote (500 feet).

Figures a-(xxviii) and a-(xxix) Waveforms for the "long line" configuration.

A1-3.4 Conclusions

From laboratory tests and simulations, it is concluded that no intolerable bit distortion is introduced into the high-speed ARINC 429 waveform due to cable lengths and stub configurations likely to be encountered on a B747-size transport aircraft.

If installations are anticipated involving longer line lengths or cables with radically different electrical characteristics, then further investigation may be required.

APPENDIX B
AN APPROACH TO A HYBRID BROADCAST-COMMAND/RESPONSE DATA BUS ARCHITECTURE

A2-1.0 Introduction

During the time that the broadcast approach to digital information transfer became established in the air transport industry, the military aviation community adopted a command/response time division multiplex technique as its standard. In this approach, all aircraft systems needing to exchange digital data are connected to a common bus and a dedicated “bus controller” determines which of them may output data on to the bus at any given time. MIL STD 1553 was written to describe this system.

The airlines considered adopting MIL STD 1553, or something like it, for use on post-1980 new civil aircraft types but found the multiplex technique to be inappropriate for such applications. In civil avionics systems, data typically flows from a given source to a single sink, or group of sinks which may be connected in a parallel, and these sinks are typically not themselves data sources. Thus there is no need for the data transfer system to provide the capability for every unit of every avionics system to both talk and listen to every other unit. The broadcast technique is adequate, and thus the airlines elected to stay with it for their new ARINC 429.

Another development in this same time frame has been the increased use by the military, particularly in transport aircraft, of avionics equipment designed originally for the airlines. This trend may be expected to continue and so give rise to the need to interface equipment providing ARINC 429 I/O capability with a MIL STD 1553A data bus system. The material in this Appendix prepared by the Information Engineering Division of the USAF Directorate of Avionics Engineering describes one way of doing this, using a data exchange buffer to compensate for the electrical, logic and timing differences between the two systems.

A2-2.0 Suggested ARINC 429/MIL STD 1553A Interface

The following is a proposed method for interfacing an avionic system employing sensors designed for any combination of ARINC 429 and MIL-STD-1553A. This method minimizes message related differences and compensates for electrical, logic and timing differences in a Data Exchange Buffer (DEB).

In a hybrid system such as shown in Figure b-(i), a signal may originate in either an ARINC 429 type subsystem or a 1553A subsystem and may be destined for either type of terminal. ARINC 429 data received by a DEB is momentarily stored and then retransmitted, complete with label, to the 1553A bus controller. The bus controller determines the intended destinations from the label and look-up table. For ARINC 429 destinations, the word is retransmitted, as received, to the appropriate DEB. For 1553A destinations, the data may be retransmitted as received or reformatted, as required by the destination subsystem. Reformatting could involve removal of label and reversing of bit order (MSB vs LSB first). Figure b-(ii) shows the handling of a word originating in the destined for ARINC 429 terminals.

Upon arrival at the appropriate destination DEB, the data is momentarily stored and then retransmitted in ARINC 429 format, complete with label, to the destination subsystem. If all labels in the system are unique, all receivers in all subsystems associated with a DEB may be connected in parallel. Only the data with the proper label will be recognized by each receiver. If labels are not unique, the DEB must have separate transmitters to transmit the data with identical labels. The desired transmitter could be specified in the 1553A subaddress field.

The retransmission of the data by the DEB allows inherently for different electrical and logical characteristics. The storage of the data allows for simultaneous reception from multiple receivers (ARINC 429 and 1553A) and retransmission when the desired bus is available. The much higher speed of 1553A would make retransmission delays small.

Figure b-(iii) illustrates the organization of a minimum system. It consists of multiple ARINC 429 receivers dumping received data into a first-in first-out (FIFO) stack, available as single LSI chips. The received data is temporarily stored and then retransmitted by the 1553A terminal. Data received via 1553A is dumped into another FIFO for retransmission by an ARINC 429 transmitter. The hardware consists only of ARINC 429 receivers, the 1553A terminal, the ARINC 429 transmitter, and as many FIFOs as are required. Hand-shaking signals available on the FIFOs eliminate almost all supporting SSI chips. This entire system would probably fit on one full ATR card or less.

Figure b-(iv) illustrates possible organization for a more sophisticated DEB. It consists of many ARINC 429 transmitters and receivers as necessary, a single (internally redundant) 1553A remote terminal, a buffer memory, a controller (microprocessor), and a program for the controller contained in ROM. Whenever a complete, valid word is available at a receiver, the controller is notified. When the parallel data bus becomes available, the word is transferred to memory. When the desired transmitter (ARINC 429 or 1553A) becomes available, the data word is routed from memory to the transmitter. The low rate of ARINC 429 terminals (minimum 320 microsec/word) would result in a very low loading of the parallel bus and controller. The speed of the 1553A terminal might necessitate a direct memory access arrangement. The controller, the program memory, the buffer memory and a dual 1553A remote terminal would probably fit on one one-sided 3/4 ATR card. The required ARINC 429 transmitters and receivers would probably fit on another card.

This method represents one way of constructing a hybrid system. The retransmission of the label with the data greatly reduces the intelligence required by the DEB but increases bus loading. A more intelligent DEB, perhaps located in the bus controller, could achieve much higher efficiencies.

A Control System View of
ARINC 429 Bus Specifications
By
T. G. Sharpe and G. E. Forquer

I. Introduction and Summary

The discussion below summarizes concepts that have grown out of an in-house effort to determine what parameter characteristics Collins feels should be included in the data standards tables of ARINC Bus Specification 429 (DITS). The DITS specification seems to be evolving as more than merely a digital bus description since in many ways it is taking on the characteristics of a system interface specification. This raises philosophical questions concerning those characteristics, which should appear in the individual equipment specifications versus those which should appear in "429". The authors cannot resolve such partitioning questions. Hopefully we can contribute, as outlined below, to an understanding of what information is required by control systems designers to achieve an acceptable system performance. The detailed discussion in this paper evolves a set of terms (outlined below) which are usable in a specification. Which of these terms appear in the individual equipment specifications and which appear in "429" remains to be determined.

At the present time, it is suggested that control system designers interfacing with digitally bused data should be concerned with three prime areas: stability considerations, signal degradation, and spectral characteristics. Without these elements of information, thorough analysis of system performance will not be possible.

The following eight parameter characteristics should prove adequate for the minimal control of interfacing considerations.

Stability

- Control Band
- Magnitude Limits
- Phase Limits

Signal Degradation

- Modification Signal to Noise Ratio (MSN)
- Static Accuracy

Spectral Characteristics

- Update Interval
- Transmit Interval
- Pre-sampling Bandwidth Limit

The following discussion of these characteristics should aid the reader in understanding their purpose and assessing their adequacy. It is recognized that some changes may necessarily take place as the industry completes its digital interfacing standardization task.

II. Stability Consideration

There is nothing uniquely digital in this area. Here our concern is with those characteristics that are most often used in linear system stability analysis – namely gain and phase characteristics. We recognize at the outset that all sensor systems are not 100% linear but this does not prevent us from defining a linear model of sufficient quality to support stability analyses. It is useful to consider here that generally the sensor will be wideband relative to the band of

APPENDIX C
DIGITAL SYSTEM GUIDANCE (PART 1)

frequencies of interest to the control system. This is necessary from a stability point of view since the converse (that is, signals narrowband relative to the control band) would introduce excessive phase lag in the control band. Thus far we have implicitly considered both bandpass and lowpass centered at zero frequency. For simplicity, however, the discussion below will assume low pass sensor characteristics but the ideas apply generally. Figure 1 illustrates an assumed sensor characteristic.

Gain and Phase Constraints

Note that prime concerns are that the gain remain essentially constant through the control band and that the phase be bounded by a linear characteristic through the control band. From a control law stability point of view, we are not concerned with what happens at frequencies above the control band because these are beyond the range where the data is being used by the control system. If we consider open loop Bode plots broken at the sensor output, the control band as used above should be wide enough to include the phase crossover as well as the gain crossover. The phase and gain characteristics provide information about phase and gain margin degradation. For most sensors the gain crossover in typical control laws is known approximately. Phase crossover is not as easily determined. A reasonable first cut would be to define the control band as approximately ten times the open loop crossover frequency with the expectation

that beyond this range control law gain is low enough to prevent gain margin problems. However, some sensors may have trouble holding a tight gain (and phase) spec over this wide a bandwidth. Possibly in these cases a loosening of the spec between open loop crossover and ten times open loop crossover may be required. With this kind of specification a simple transport delay in combination with a gain change can be used for stability analysis or, for slightly more complex cases, simple transfer functions can be used to approximately fit the spec. The important point here is not to constrain the sensor designer to a first order or second order or any specific implementation, but to rather bound in a simple yet usable sense the stability degradation the sensor can introduce. The important stability characteristics are defined concisely below.

- Control Band – That band of frequencies over which magnitude and phase characteristics of the sensor are important to the control system stability.
- Magnitude Constraint – The bounds (envelope) on the permissible gain variation in a linear frequency response sense that are permissible over the control band.
- Phase Constraint – The bounds (envelope) on the permissible phase variation in a linear frequency response sense that are permissible over the control band.

Figure 1. Gain and Phase Limits of Interest to Control System Designer

APPENDIX C
DIGITAL SYSTEM GUIDANCE (PART 1)

Potential Measurement Technique

These quantities could be measured by providing a sinusoidal input stimuli at selected frequencies in the control band using a mid-range amplitude. At each frequency the output component of interest (assuming some distortion) will be the output component whose frequency corresponds to the input frequency. The phase and amplitude of this component of this component relative to the forcing function will provide the magnitude and phase information. In the terminology of nonlinear system analysis, this procedure yields an empirically derived describing function for the sensor over the control band. If amplitude dependent nonlinearities are severe, more than one amplitude of forcing function may have to be used with the procedure repeated at each amplitude.

III. Signal Degradation

In this area we are concerned with what the sensor may have done to degrade the signal. The thrust here is not stability but performance. Figure 2 presents a view of sensor and signal characteristics that is useful in this context. In Figure 2 some important sources of signal degradation are illustrated. The term "noise" is used somewhat loosely in Figure 2 to denote degradation sources. Process noise and installation noise are inherent in the signal impinging on the sensor – the former being things such as gust noise and beam noise and the latter being effects such as EMI, mounting errors, etc. Within the sensor itself there is internally generated noise such as shot noise from resistors, EMI from digital buses, etc. that is independent of the input signal. In a radio receiver this is the kind of noise that is measured at the output when the input is shorted. Note that this "noise" can also include bias and drift effects. If there is a digital sampling process in the sensor, some aliasing of the input signal spectrum will occur. This aliased energy may also be regarded as noise.

The other inherent sensor degradation is more difficult to deal with, however, for it is signal dependent. A familiar analog example is input amplitude dependent characteristics such as saturation effects that only become significant above certain input amplitudes. Another is nonlinearities that produce harmonic distortion under sine wave excitation as shown in the example below.

**Figure 2. Sensor and Signal Characteristic
and Measurement Noise**

APPENDIX C
DIGITAL SYSTEM GUIDANCE (PART 1)

Harmonic Distortion

Consider square law distortion in an otherwise linear sensor. Let the sensor output be:

$$y(t) = x(t) + kx(t)^2$$

Where $x(t)$ is the sensor input and let $x(t) = \sin\omega t$. Then

$$y(t) = \sin\omega t + k\sin^2\omega t$$

$$y(t) = \sin\omega t \pm \frac{k}{2} \mp \frac{k}{2} \cos 2\omega t$$

Note that d.c. and second harmonic components as well as the forcing frequency appear at the output. In digital systems a similar effect occurs when multiple rates are introduced, such as signals being received at one rate from a digital bus and being used at a different rate by a software program. If the analog signals originally sampled and put on the bus were sinusoidal at one frequency then, in general, frequency components less than and greater than the input frequency (as well as the input frequency) appear after the second sampler. The amplitude and number of these spurious outputs is a function of the two sampling rates as well as the input frequency. The net effect of all such internal sensor effects is observable by subtracting sensor input from sensor output to yield measurement error as shown in Figure 2.

Measurement Error

The involved nature of what can happen to the signal within the sensor as shown in Figure 2 is the source of ambiguity in conventional “accuracy” specs. Since measurement noise can be dependent on input amplitude as well as spectral characteristics, it is not possible to specify it with a single and simple metric. It should also be apparent that measurement error must be addressed statistically since a significant portion of the input, process noise, is only describable as a random process.¹ Technically the input signal is also in general a random processes influenced by such things as the gust striking the aircraft. Gusts also can only be described as random processes.

To evaluate the spectral characteristics of measurement error will require tests which force the system with noise type inputs. Exponentially correlated noise of specified variance and correlation time (or bandwidth) should be sufficient in most cases. If a sensor is known to be susceptible to a specific type of noise, however, that noise should be included in the test. Often it will be useful to separate out the low frequency or d-c components of measurement error since these may be more tolerable in some applications than dynamic errors. A set of tests that will measure these characteristics is described below.

Modified Signal to Noise Ratio (MSN)

Force the sensor with random noise of specified rms value (σ) and correlation time (τ). Determine the power spectral density (PSD) of the input signal to the sensor. Determine the PSD of the measurement error. Plot the two PSD's on a common plot as shown in Figure 3. Define a modified signal to noise ratio (which will be a function of frequency) as the square root of noise ratio at each frequency of signal PSD amplitude to measurement error PSD. Note in the example shown in Figure 3 there is a bulge in the measurement error around zero frequency. This effect would indicate d-c bias and possibly low frequency bias drift from the sensor. This effect may or may not be important depending on whether the application permits washing out low frequency components, e.g. in a complementary filter. In the range of frequencies where accurate sensor response is required, it is suggested that appropriate values for the modified signal to noise (MSN) will be 100 to 1000. Roughly, these numbers correspond

¹ Recognizing that a complete description of a random process includes not only probability distributions but also spectral characteristics.

APPENDIX C
DIGITAL SYSTEM GUIDANCE (PART 1)

to noise power being 1% to .1% of signal power at each frequency or noise being 40 to 60 db down from signal. The relationship between MSD and ordinary signal to noise can be understood by assuming both signal and noise PSD's are flat over a band of frequencies Δw as shown in Figure 3. Let the value of the signal PSD in this band be S_o , then rms signal power in the band Δw is given by $\sqrt{S_o * w}$. Similarly, rms error power is given by $\sqrt{P_o * w}$. Therefore conventional signal to noise over the band w is given by $\sqrt{\frac{S_o}{P_o}}$. Requiring that this signal to noise be 100 is equivalent to requiring that noise power be 1% of signal power over this band. Carrying this back to the MSN implies that $MSN(w) = \sqrt{\frac{S_o}{P_o}} = 100$ over the band Δw . The above also represents the motivation for considering square root of the ratio than the ratio directly.

Amplitude Dependent Nonlinearities

The approach described above tests for input frequency dependent degradations by providing a realistic input spectrum. It should be realized that if there are amplitude dependent degradations, the MSN analysis will yield different answers depending on the rms value of the input noise. It is suggested that the MSN measurement be done with worst case input noise, i.e., largest rms and bandwidth that will be encountered. In some cases alternate MSN specs for different flight regimes may be appropriate.

In many cases a more explicit presentation of the amplitude dependent non-linearities may be desirable. A good example here is localizer receiver linearity, specified as being linear within a given percentage up to .155 DDM, a larger percentage from .155 to .310 DDM and not decreasing between .310 and .400 DDM. Such a specification is important in defining localizer capture laws, where one can begin "using" the signal crudely before it is linear or precisely accurate. It should be noted that this is a slightly different use of sensor data than for precise state control, i.e. the control is carrying the system to a prescribed state rather than maintaining it at a prescribed state in the presence of noise. Normally the latter operation will require more accurate information from the sensor. The amplitude dependent degradations should be measured statically -- that is, one should provide a test input at specified amplitude, allow transients to settle, and measure the output value.

The important signal degradation terms are defined concisely below. Only the last two are proposed as parameter characteristics--the first three being definitions to clarify the last two.

- Measurement Error – The difference between the signal impinging on the sensor and the output representation of that signal by the sensor expressed in consistent units.
- Signal PSD (SPSD) – The power spectral density of the signal impinging on the sensor.
- Measurement Error PSD (MEPSD) – The power spectral density of measurement error introduced by the sensor.
- Modified Signal to Noise Ratio – A measure primarily of the spectral characteristics of sensor errors defined as the square root of the ratio of SPSD and MEPSD at each frequency in the control band.

$$\text{i.e., } MSN(w) = \sqrt{\frac{SPSD(w)}{MEPSD(w)}}$$

- Static Accuracy – A measure of the amplitude dependent characteristics of sensor errors defined as the difference between input and output signals after all transients have settled.

Potential Measurement Technique

Modified Signal to Noise (MSN) determination requires assuming a random process model for the signal impinging on the sensor. Normally an exponentially correlated signal with specified variance will be sufficient. Empirically determined power spectral densities (using discrete Fourier Transform techniques) will need to be measured for input signal as well as measurement error. Static accuracy measurement was described above.

APPENDIX C
DIGITAL SYSTEM GUIDANCE (PART 1)

IV. Spectral Characteristics

In this area the digital nature of the system interface must be faced squarely. The control system designer cannot alter the signal degradation introduced by the sensor whether it be due to nonlinearities, aliasing, noise, etc. He has great potential, however, for making matters worse if he is not alert to potential aliasing problems that he may introduce. To analyze aliasing precisely he would need a precise definition of the spectrum of each signal being received on the digital bus including the update interval for each signal. A more practical approach is to place an upper bound on the received signal spectrum and then ensure downstream performance is adequate using this bound as the signal spectrum. These ideas are made more precise below.

Figure 3. Modified Signal to Noise Ratio

Multirate Sampling

A simple model for signals received from a bus and used in a digital processor is shown in Figure 4. We note that the spectrum of the signal on the bus, $F_1(s)$, is an infinitely replicated version of the analog input spectrum with replicas spaced by the input sampling frequency F_1 . We cannot, therefore, speak of the bandwidth of $F_1(s)$ strictly. What we mean here is that a bound is required on each copy in $F_1(s)$. Deriving the spectrum of the signal $F_2(s)$ is beyond the scope of this discussion but a technique has been developed that will yield this spectrum, $F_2(s)$, given the quantities F_1 , F_2 , and the shape of the repeated spectrum of $F(s)$ in $F_1(s)$. There is considerable spreading of signal energy in this process with considerable “aliasing” potential even if the quantity f_c in Figure 4 is much less than the Nyquist frequency $(\frac{f_1}{2}, \frac{f_2}{2})$ for both F_1 and F_2 . The “aliasing” in the spectrum $F_2(s)$ occurs because the second sampler is not operating on a properly band limited function (see Figure 4) due to the “infinite replica” nature of the spectrum $F_2(s)$.

Deterministic Versus Random Signals

The discussion above did not specify whether the original analog quantity was a deterministic signal or a random process. For deterministic cases we deal with the Fourier transforms of the signals involved. However, as pointed out in Section III the signals of interest are really describable only in terms of random processes. For this case the development must proceed in terms of power spectral density of the signals involved. Figure 5 then illustrates the bound on bused signal PSD that is envisioned. Recall that white noise through a lowpass filter yields a PSD that rolls off at 40 db/decade as shown below.

APPENDIX C
DIGITAL SYSTEM GUIDANCE (PART 1)

White Noise Input PSD: $U(S) = A - \infty < w < +\infty$

Filter Transfer Function: $T(jw) = \frac{1}{j\tau w + 1}$

Output PSD: $Y(S) = T(S)T^*(S)U(S)$

$$Y(w) = \frac{A}{\tau^2 w^2 + 1}$$

Adequate roll off characteristic of the digitally bused data reduces the aliasing problem of the second sampler if the second sampling is properly performed. However, not only this spectrum but also the frequency F_1 enters into the aliasing in $F_2(s)$, therefore, it is desirable also to carefully specify F_1 . This will be accomplished through the update interval. Assuming F_2 is somewhat fixed by computer speed and loading considerations, aliasing can be minimized for a given input spectrum by making F_1 as high relative to F_2 as possible.

The important spectral characteristic terms are defined concisely below.

- Update Interval – The cyclic time interval, as measured at the DITS bus interface, between transmissions of new freshly sensed and converted/derived values of the parameter.

Figure 4 Analysis of Multirate Sampling

- Transmit Interval – The cyclic time interval, as measured at the DITS bus interface, between transmissions of the parameter. Transmit Interval \leq Update Interval.

APPENDIX C
DIGITAL SYSTEM GUIDANCE (PART 1)

- Pre-sampling Bandwidth Limit – That bandwidth for a first order lag that will upper bound the spectral characteristics of the signal of the signal on the bus.

Dear Rick:

The enclosed paper is a revised version of "Design Parameters for Digital Avionic Systems," which was originally circulated with AEEC letter 79-022/SAI-99. The revision addresses the topic of aliasing which could occur when reducing the sampling rate of a digitally encoded signal. This topic was discussed at the DITS working group meeting held on April 18 and 19.

Sincerely

DESIGN PARAMETERS FOR DIGITAL AVIONIC SYSTEMS

Prepared by
Boeing Commercial Airplane Company
REVISION A

Summary

This paper explains the necessity for defining presampling filter characteristics, transport delays and minimum update rates for digital and noise characteristics are discussed. A design procedure for selecting the required filter characteristic and update rate is presented.

Introduction

The new generation of commercial aircraft will use digital technology to implement many functions, which were traditionally performed with analog hardware. These functions include inner and outer servo loops for aircraft control and guidance, processing and filtering signals from navigation and other sensors, and filtering of data prior to its display on cockpit instruments. Digital technology will also replace the majority of the formerly analog communication paths between systems, sensors, instruments and actuators.

A basic property of these and other digital systems is that they only process or transfer values of data from discrete points in time. The contrast between the discrete time nature of a digital system and the continuous time nature of an analog system is shown in Figure 1. Analog systems are said to operate in the continuous time domain while digital systems are said to operate in the discrete time domain.

In order for discrete time digital systems to be used to process or transfer the inherently continuous time data from real world physical systems, samples of the continuous data must be taken at periodic intervals. These samples from discrete points in time can then be used as the input to the discrete time digital system. It is intuitively obvious that the interval between samples affects the accuracy with which the continuous time data is represented by the discrete samples. It is also obvious that rapidly varying signals should be sampled more often than slowly varying signals in order to maintain an adequate representation of the continuous analog data. Selection of a proper sampling rate for each signal is a design task unique to digital systems. An understanding of the Sampling Theorem is necessary in order to make the proper trade offs between sampling rate, signal-to-noise ratio, signal delay, and system complexity.

The Sampling Theorem

The Sampling Theorem states that a signal which contains no frequency components higher than f_o Hertz can be exactly recovered from a set of its samples if the samples are spaced no further apart than $\frac{1}{2} f_o$ seconds. This is equivalent to requiring that the sampling frequency be greater than twice the highest frequency component of the signal.

The reason for this requirement can be shown by examining the frequency spectrum of the sampler output. Modeling the sampling operation as the multiplication of the input signal by an impulse train as shown in Figure 2 allows the sampler output spectrum to be computed from a Fourier Transform identity. The required identity states that time domain multiplication is equivalent to frequency domain convolution. Therefore, the output spectrum is found by convolving the input spectrum with the spectrum of the impulse train. This relationship is shown in Figure 3. The convolution operation has the effect of reproducing the spectrum of the input signal about zero frequency and at all harmonics of the sampling frequency. If the sampling frequency, $1/T_s$, is greater than twice f_o the spectral components centered about the sampling frequency and its harmonics will not overlap the spectral component centered about zero frequency. Therefore, the spectral component centered about zero, which is identical to the input spectrum, can be obtained by passing the sampled output through a low pass filter with a bandwidth of f_o Hz.

Application of the Sampling Theorem to Digital Avionics Systems

The discussion of the Sampling Theorem in the preceding section has shown that a signal which contains no frequency components higher than f_o Hz. can be exactly represented by a series of samples spaced no further apart than $\frac{1}{2} f_o$ seconds. However, signals, which represent physical quantities, such as those processed by avionic systems never satisfy the strict bandwidth limitation requirement stated above. Therefore exact reproduction of the original signal from its samples is not possible. The effect of the non-bandlimited nature of signals is to distort the replica reconstructed from the samples. The shaded area shown in Figure 4 represents typical high frequency signal energy

APPENDIX D
DIGITAL SYSTEM GUIDANCE (PART 2)

which distorts the low frequency portion of the signal spectrum. The high frequency portion of the signal takes on the identity of the lower frequencies, hence the name “aliasing” for this phenomenon.

Aliasing becomes a greater problem when the signal is corrupted by noise, which has a wider bandwidth than the signal. When this occurs both signal energy and noise energy which is beyond one half of the sampling frequency is aliased into the low frequency portion of the recovered signal. This effect is shown in Figure 5. The signal-to-noise ratio is degraded by both noise and signal components which are aliased into the low frequency portion of the signal spectrum. The effect of aliasing can be decreased by sampling the incoming signal at a higher rate and/or using a presampling filter to reduce the bandwidth of the signal prior to sampling. Neither of these approaches can ever completely eliminate the effect of aliasing and they each result in some negative impact on the overall system.

An increase in the sampling rate requires more computations to be done in a given period of time. This requires more computational resources, which increases the weight, complexity, and power requirements of the computer subsystems. The use of a presampling filter to limit the bandwidth prior to sampling distorts the signal. It also increases the delay experienced by signals as they propagate through the system. The increase in delay reduces phase margin if the signal is used in a closed loop control system. Therefore, more stringent delay requirements must be placed on other components in the loop if the system phase margin is to remain constant.

Design Tradeoffs for Digital Avionics Systems

The final choices of sample rate and presampling filter depend upon the input signal and noise spectra, maximum allowable signal-to-noise ratio degradation due to aliasing, maximum allowable transport delay, available computational resources, and the bandwidth of the system which uses the data. A practical way to make these choices is to analyze the system for various sample rates and filters. This can best be done with the aid of a computer program which computes the effect of each combination of sample rate and filter characteristic on the output signal-to-noise ratio for the defined input signal and noise spectra.

The initial computation is to determine the effect of the prefilter on the in-band signal-to-noise ratio without regard to aliasing effects. A typical plot of signal-to-noise ratio versus presampling filter bandwidth is shown in the top curve of Figure 6. This curve forms a baseline against which signal-to-noise ratio degradation caused by aliasing can be compared. The signal-to-noise ratio is determined by computing the input signal power and input noise power, which is passed by the selected prefilter. This parameter will generally exhibit a peak value at a specific bandwidth. The signal-to-noise ratio will decrease with increasing bandwidth as more noise is admitted and decrease with decreasing bandwidth as signal energy is eliminated.

The filter order is an important design parameter because higher order filters roll off more rapidly near the cutoff frequency. Therefore higher order filters admit less noise and signal from beyond the cutoff frequency than low order filters. Because of this characteristic, high order filters alias no more noise into the signal than slightly narrower bandwidth low order filters. However, high order filters delay the signal more than low order filters.

The ultimate objective of the design task discussed in this paper is to achieve acceptable system performance with the minimum possible sampling rate. System performance is adversely affected by large propagation delays and high in-band noise levels.

If the maximum allowable propagation delay is given, the minimum usable filter bandwidth can be found standard plots of group delay versus frequency for the type and order of filter considered. (See for example Reference 1, page 112.) This minimum bandwidth is plotted on Figure 6 as a vertical line. The maximum achievable signal-to-noise ratio is constrained by the requirement for a presampling filter wide enough to limit delay to the given value. The intersection of the minimum bandwidth line with the top curve of Figure 6 gives the maximum achievable signal-to-noise ratio i.e., the signal-to-noise ratio which would be achieved by an unsampled system.

Sampling rate is chosen by comparing the maximum acceptable degradation in signal-to-noise ratio to the actual aliasing degradation due to sampling at the candidate rates. For the example shown in Figure 6, a sampling rate of 50Hz would be chosen.

A system interface which meets prescribed limits on signal delay and maximum noise due to aliasing can be designed using the procedures outlined above. Some systems which use sampled data, such as closed loop control systems, have a bandwidth which is much smaller than that of the sampling filter. For this reason it is important to verify that the signal and noise power which is aliased into the frequency band of interest is well below the inherent noise in that band.

This can be accomplished by constructing a signal and noise power spectral density plot for the filter and sampling rate chosen. The power spectral density plot is most easily obtained with the aid of a computer program. A typical plot of this type is shown in Figure 7. The example power spectral densities in Figure 7 show that the aliased signal and noise

APPENDIX D
DIGITAL SYSTEM GUIDANCE (PART 2)

is much lower than the inherent noise level in the frequency range of interest. If this constraint is not met a different combination of filter and sampling frequency must be chosen.

In some situations it may be desired to reduce the sampling rate of a digitally encoded signal. This may be done where wideband digital data is used to drive an instrument or subsystem which responds only to narrower bandwidth data. Simple deletion of unwanted samples to reduce the sampling rate can cause aliasing problems similar to those encountered when sampling an analog signal at an insufficient rate. The aliasing can be elimination of the unwanted samples. Design of the digital filter is subject to the same set of delay versus aliasing noise tradeoffs as the design of an analog presampling filter.

Conclusion

The procedures outlined in this paper can be used to choose the presampling filter and sampling rate required for interfaces to a digital signal processing or control system. The values are chosen to meet the constraints of maximum allowable delay and maximum allowable noise due to aliasing. Signal and noise spectra of the signal to be sampled must be supplied as an input to the design procedure.

APPENDIX E GUIDELINES FOR LABEL ASSIGNMENTS

The ARINC 429 data bus was developed to provide a standardized means of digital information transfer between the "ARINC 700" series of avionics units. ARINC 429 has proven to be a very flexible standard and its usage has extended to provide data transfer between Line Replaceable Units (LRU) which are not otherwise covered by ARINC Characteristics. It is important that each new usage of ARINC 429 be coordinated and indexed by ARINC such that the information on usage (label allocation, data format, etc.) is available industry-wide. The use of the same label for two different functions on a particular LRU type built by different manufacturers can create serious problems.

To facilitate the coordination of ARINC 429 label usage between the industry and the ARINC staff, a set of guidelines is provided.

1. New labels should be selected from the five character field as defined in Section 2.3 (three octal and three hexadecimal).
2. The following labels have special significance and should not be used: label 000 (not used) and label 377 (equipment identification). The preferred SSM encoding for method for the Equipment Identification Word (label 377) is according to the Discrete word guidelines. When this label was originally assigned, it was recognized as a non-BNR word. The SSM encoding was according to the BCD and DISC guidelines that were identical at that time. During development of Supplement 4, the SSM for DISC was revised to its current form to provide enhanced failure warning. When the SSM encoding was changed, some systems retained the BCD encoding for the Equipment Identification word and others changed to DISC encoding.
3. The following labels are presently "spare" and should only be used for new parameters which may have very widespread usage throughout the airplane architecture.

005	040	050	054	107	163	227	371
006	046	051	055	113	167	240	
007	047	052	057	124	226	243	

4. Where possible, similar word usage should be "grouped"; for example, if Engine N 1 is to be provided from a new unit (PMUX) it should utilize label 246 which is presently N 1 (engine direct).
5. Where possible, grouped usage should have identical data specification (units, range, significant digits/bits, positive sense, resolution, min--max transmit interval). To facilitate this commonality it is permissible for a particular LRU to output a lower resolution signal (fewer significant digits/bits) if the least significant remainder of the data field is set to zeros.
6. Where word grouping is not possible, the labels should be selected from the following subgroups:

Binary coded decimal (BCD) sub-group 001 to 067, 125, 165, 170, 200, 201, 230 to 237.

Binary (BNR) subgroup 070 to 124, 126 to 144, 150 to 154, 162 to 164, 166, 167, 171 to 177, 202 to 227, 240 to 257, 262 to 265, 267, 310 to 347, 360 to 376.

Mixed BCD and BNR subgroup 260, 261

Discretes subgroup 145 to 147, 270 to 276

Maintenance and discrete data subgroup 155, 156

Maintenance data subgroup 157 to 161, 350 to 354

Test word subgroup 266, 277

Application dependent subgroups 300 to 307

Acknowledgement subgroup 355

Maintenance ISO #5 subgroup 356

ISO #5 message subgroup 357

A schematic of these subgroups is attached.

APPENDIX E

GUIDELINES FOR LABEL ASSIGNMENTS

- 7. Allocation of bits within words, as defined in the appropriate sections.
 - BCD
 - BNR
 - Discretes
 - Maintenance data
 - Test
 - Application dependent
 - Acknowledgement
 - Maintenance ISO #5
 - ISO #5 message
 - 8. The data should be fully defined by Equipment ID and the label and the Source Destination Indicator (SDI). It should not be necessary to decode additional bits in the word to correctly interpret the data field.
 - 9. The equipment ID should be allocated as the two least significant digits of the 7XX ARINC equipment specification, if one exists. For equipment not otherwise covered by an ARINC Specification, an equipment ID should be allocated with a non-numeric value of the hexadecimal character set as the least significant digit.
 - 10. Equipment ID of 000 (HEX) should not be used.
 - 11. The SDI code should indicate the aircraft installation number of the source equipment, in a multi-system installation, as described in 2.1.4.

SUPPLEMENT 18
TO
ARINC SPECIFICATION 429
DIGITAL INFORMATION TRANSFER SYSTEM (DITS)
PART 1
FUNCTIONAL DESCRIPTION, ELECTRICAL INTERFACES,
LABEL ASSIGNMENTS AND WORD FORMATS

Published: November 29, 2012

Prepared by the AEEC

Adopted by the AEEC Executive Committee:

October 4, 2012

A. PURPOSE OF THIS DOCUMENT

Supplement 18 represents a significant update to ARINC 429. It provides new ARINC 429 word assignments, as well as updates to the general format of the document, label assignments, equipment IDs, and System Address Labels (SAL). Editorial changes are made for improved readability.

B. ORGANIZATION OF THIS SUPPLEMENT

In this document **blue bold** text is used in some instances to indicate those areas of text changed by the current Supplement only.

C. CHANGES TO ARINC SPECIFICATION 429 INTRODUCED BY THIS SUPPLEMENT

This section presents a complete listing of the changes to the document introduced by this Supplement. Each change is identified by the section number and the title as it will appear in the complete document. Where necessary, a brief description of the change is included.

Section 1 – Introduction

This section was updated to reflect the latest ARINC Standard format. Editorial changes were made for improved readability.

Section 2 – Digital Information Transfer System Standards

This section was updated to reflect the latest ARINC Standard format. Editorial changes were made for improved readability.

Section 3 – Application Notes

This section was updated to reflect the latest ARINC Standard format. Editorial changes were made for improved readability.

Attachment 1-1 – LABEL CODES

ARINC 429 labels codes have been added as follows:

Code No. (Octal)	Equip ID (Hex)	Parameter	Data
045	055	Message Block Start	BLK – BNR
046	055	Message Block Data	BLK – BNR
076	0F1	Fire Warning Computer	BNR
114	055	Lateral Protection Level	BNR
115	055	Vertical Protection Level	BNR
127	055	FAS Vertical Alarm Limit	BNR
130	055	MLS Aux Data Part 1 Group A	BNR

Attachment 1-2 – EQUIPMENT CODES

Equipment ID codes have been added as follows:

Equip ID (Hex)	Equipment Type
068	Integrated Surveillance System (ARINC 768)
09A	On-Board Airport Ground Navigation (Airbus)
0A5	AHRS Controller (ARINC 705)
0E1	Cargo Door Control (Boeing 777)
0E2	Enhanced Vision System
0E3	AN/APN-232 Radar Altimeter (C-135)
0F1	Fire Detection and Suppression System
131	Primary Flight Display
139	Cockpit Door Surveillance System
148	Airline Network Infrastructure (Airbus)
14D	Integrated Air System Controller (Boeing 747-8)
15F	Cooled Service Air System (CSAS)
172	Lateral Control Electronics Unit (Boeing 747-8)
17D	Master Galley Control (MGC) (A330,A340, A380)
17E	On-board Oxygen Generation System (OBOGS) (A330, A340, A380)
17F	Nitrogen Generation System Control
181	Satellite Communication Antenna (ARINC 781)
1AE	Yaw Damper Stabilizer Trim Module (Boeing 747-8)
2BA	GENx-2B Electronic Engine Control (EEC) Channel A
2BB	GENx-2B Electronic Engine Control (EEC) Channel B

Attachment 2A – DATA STANDARDS - BCD Data

The following labels were modified:

Label	Equip ID (Hex)	Parameter Name	Range (Scale)	Sig Bits	Transmit Interval	Pos Sense
017	055	Selected Runway Heading	0-359.9	4	167 – 333 msec	Always Positive
035	055	Paired DME Frequency		4	100 – 200 msec	Always Positive
036	055	MLS Channel Selection	500-699	3	100 – 200 msec	Always Positive

Attachment 2B – DATA STANDARDS - BNR Data

The following labels were added or modified:

Label	Equip ID (Hex)	Parameter Name	Units	Range (Scale)	Sig Bits	Resolution	Transmit Interval	Pos Sense
105	055	Selected Runway Heading	Degrees	±180	11	0.1	167 – 333 msec	CW-N
114	055	Lateral Protection Level	Meters	0 – 163.83	14	0.01	66.6 – 240 msec	Always Positive
115	055	Vertical Protection Level	Meters	0 – 163.83	14	0.01	66.6 – 240 msec	Always Positive
116	055	Horizontal GLS Deviation rectilinear	Feet	±24000	18	0.0915	33.3 – 66.6 msec	Fly Right
117	055	Vertical GLS Deviation rectilinear	Feet	±1024	14	0.0625	33.3 – 66.6 msec	Fly Down
127	055	FAS Vertical Alarm Limit	Meters	0 – 102.3	10	0.1	66.6 – 240 msec	Always Positive
130	055	MLS Aux Data Part 1 Group A	N/A	N/A	N/A	N/A	125 – 250 msec	N/A
131	055	MLS Aux Data Part 2 Group A	N/A	N/A	N/A	N/A	125 – 250 msec	N/A
132	055	MLS Aux Data Part 3 Group A	N/A	N/A	N/A	N/A	125 – 250 msec	N/A
133	055	MLS Aux Data Part 4 Group A	N/A	N/A	N/A	N/A	125 – 250 msec	N/A
134	055	MLS Aux Data Part 1 Group B	N/A	N/A	N/A	N/A	125 – 250 msec	N/A
135	055	MLS Aux Data Part 2 Group B	N/A	N/A	N/A	N/A	125 – 250 msec	N/A
136	055	MLS Aux Data Part 3 Group B	N/A	N/A	N/A	N/A	125 – 250 msec	N/A
137	055	MLS Aux Data Part 4 Group B	N/A	N/A	N/A	N/A	125 – 250 msec	N/A
140	055	MLS Aux Data Part 1 Group C	N/A	N/A	N/A	N/A	125 – 250 msec	N/A
141	055	MLS Aux Data Part 2 Group C	N/A	N/A	N/A	N/A	125 – 250 msec	N/A
151	055	MLS AZ Deviation	mV	±2400	15	0.0732		Flight Right
152	055	MLS GP Deviation	mV	±2400	15	0.0732		Flight Down
164	055	MLS Absolute Glide Path Angle	Degrees	±41	15	0.00125	25 – 66.6 msec	Above Horizon
165	055	MLS Absolute Azimuth Angle	Degrees	±82	16	0.00125	25 – 100 msec	L of Course
167	055	FAS Lateral Alarm Limit	Meters	0 – 102.3	10	0.1	66.6 – 240 msec	Always Positive

173	055	Localizer Deviation	DDM	±0.4	12	0.0001	33.3 – 66.6 msec	Fly Right
174	055	Glide Slope Deviation	DDM	±0.8	12	0.0002	33.3 – 66.6 msec	Fly Down
177	055	Distance to LTP/FTP	Nmiles	±512	16	0.007812	83.3 – 167 msec	Positive
240	055	Selected Glide Path Angle	Degrees	0 – 180	15	0.0055	800 – 1600 msec	Always Positive
241	055	Threshold Crossing Height	Meters	0 – 1638.35	20	0.00156	800 – 1600 msec	Always Positive
245	055	FTP to GARP Distance	Meters	0 – 104857.5	20	0.1	800 – 1600 msec	Always Positive
250	055	Unflagged Horizontal Deviation Rectilinear	Feet	±24000	18	0.0915	33.3 – 66.6 msec	Fly Right
251	055	Unflagged Vertical Deviation Rectilinear	Feet	±1024	14	0.0625	33.3 – 66.6 msec	Fly Down
320	055	Aircraft Altitude	Feet	131072	20	0.125	100 – 200 msec	Positive
325	055	Anchor Point Latitude	Degrees	±180	20	0.000172	800 – 1200 msec	North
326	055	Anchor Point Longitude	Degrees	±180	20	0.000172	800 – 1200 msec	East
327	055	Anchor Point Altitude	Feet	131072	20	0.125	800 – 1200 msec	Up
330	055	FLS Beam Slope	Degrees	±10	10	0.01	800 – 1200 msec	Always Negative
331	055	Local Magnetic Deviation	degrees	±180	18	0.000687	800 – 1200 msec	East
333	055	Runway Threshold Latitude	Degrees	±180	20	0.000172	800 – 1200 msec	North
334	055	Runway Threshold Longitude	Degrees	±180	20	0.000172	800 – 1200 msec	East
335	002	Track Angle Rate	Deg/Sec	±32	11			CW
335	004	Track Angle Rate	Deg/Sec	±32	11			CW
335	005	Track Angle Rate	Deg/Sec	±32	11			CW
335	038	Track Angle Rate	Deg/Sec	±32	11			CW
335	055	Aircraft Altitude Fine	Degrees	0.000172	11	8.38E-8	100 – 200 msec	Positive
335	056	Track Angle Rate	Deg/Sec	±32	11			CW
335	060	Track Angle Rate	Deg/Sec	±32	11			CW
336	055	Aircraft Longitude Fine	Degrees	0.000172	11	8.38E-8	100 – 200 msec	Positive
370	055	GNSS Height	Feet				500 – 1200 msec	

Attachment 9A – GENERAL AVIATION LABELS AND DATA STANDARDS

The content of this attachment was deleted by Supplement 18. Note added to refer to GAMA website.

Attachment 9B – GENERAL AVIATION WORD EXAMPLES

The content of this attachment was deleted by Supplement 18. Note added to refer to GAMA website.

Attachment 9C – EQUIPMENT IDENTIFIERS

The content of this attachment was deleted by Supplement 18. Note added to refer to GAMA website.

Attachment 11 – SYSTEM ADDRESS LABELS

The following System Address Labels (SALs) are added by Supplement 18:

System Address Label (Octal)	System
140	MFP-1 (Multi-Functional Probe)
141	SSA-1 (Side Slip Angle Probe)
142	ISP1-1 (Integrated Static Probe)
143	ISP1-2 (Integrated Static Probe)
144	MFP-2 (Multi-Functional Probe)
145	SSA-2 (Side Slip Angle Probe)
146	ISP2-1 (Integrated Static Probe)
147	ISP2-2 (Integrated Static Probe)
150	MFP-3 (Multi-Functional Probe)
151	SSA-3 (Side Slip Angle Probe)
153	ISP3-1 (Integrated Static Probe)
154	ISP3-2 (Integrated Static Probe)
155	On-board Airport Navigation System (OANS)
231	SDU ORT #1
232	SDU ORT #2
317	AFIRS (Automated Flight Information Reporting System)
335	Cursor Control Device (CCD) Left - 1
336	Cursor Control Device (CCD) Right - 2
337	Smoke Detection System (B-767)
346	Integrated Air System Controller
347	Landing Gear Control & Interface Unit (LGCIU) (Airbus)

APPENDIX X – CHRONOLOGY AND BIBLIOGRAPHY

This appendix deleted by Supplement 18.

ARINC Standard – Errata Report

1. Document Title

(Insert the number, supplement level, date of publication, and title of the document with the error)

2. Reference

Page Number: _____ Section Number: _____ Date of Submission: _____

3. Error

(Reproduce the material in error, as it appears in the standard.)

4. Recommended Correction

(Reproduce the correction as it would appear in the corrected version of the material.)

5. Reason for Correction (Optional)

(State why the correction is necessary.)

6. Submitter (Optional)

(Name, organization, contact information, e.g., phone, email address.)

Please return comments to fax +1 410-266-2047 or standards@arinc.com

Note: Items 2-5 may be repeated for additional errata. All recommendations will be evaluated by the staff. Any substantive changes will require submission to the relevant subcommittee for incorporation into a subsequent Supplement.

[To be completed by IA Staff]

Errata Report Identifier: _____ Engineer Assigned: _____

Review Status: _____

ARINC Project Initiation/Modification (APIM)

1.0	Name of Proposed Project (Insert name of proposed project.)	APIM #: _____
1.1	Name of Originator and/or Organization (Insert name of individual and/or the organization that initiated the APIM)	
2.0	Subcommittee Assignment and Project Support	
2.1	Suggested AEEC Group and Chairman (Identify an existing or new AEEC group.)	
2.2	Support for the activity (as verified) Airlines: (Identify each company by name.) Airframe Manufacturers: Suppliers: Others:	
2.3	Commitment for Drafting and Meeting Participation (as verified) Airlines: Airframe Manufacturers: Suppliers: Others:	
2.4	Recommended Coordination with other groups (List other AEEC subcommittees or other groups.)	
3.0	Project Scope (why and when standard is needed)	
3.1	Description (Insert description of the scope of the project.)	
3.2	Planned usage of the envisioned specification Note: New airplane programs must be confirmed by manufacturer prior to completing this section.	
New aircraft developments planned to use this specification		yes <input type="checkbox"/> no <input type="checkbox"/>
Airbus: (aircraft & date)		
Boeing: (aircraft & date)		
Other: (manufacturer, aircraft & date)		
Modification/retrofit requirement		yes <input type="checkbox"/> no <input type="checkbox"/>
Specify: (aircraft & date)		
Needed for airframe manufacturer or airline project		yes <input type="checkbox"/> no <input type="checkbox"/>
Specify: (aircraft & date)		

Mandate/regulatory requirement yes no

Program and date: (program & date)

Is the activity defining/changing an infrastructure standard? yes no

Specify (e.g., ARINC 429)

When is the ARINC standard required?
 _____ (month/year) _____

What is driving this date? _____ (state reason) _____

Are 18 months (min) available for standardization work? yes no

If NO please specify solution: _____

Are Patent(s) involved? yes no

If YES please describe, identify patent holder: _____

3.3 Issues to be worked

(Describe the major issues to be addressed.)

4.0 Benefits

4.1 Basic benefits

Operational enhancements yes no

For equipment standards:

(a) Is this a hardware characteristic? yes no

(b) Is this a software characteristic? yes no

(c) Interchangeable interface definition? yes no

(d) Interchangeable function definition? yes no

If not fully interchangeable, please explain: _____

Is this a software interface and protocol standard? yes no

Specify: _____

Product offered by more than one supplier yes no

Identify: (company name)

4.2 Specific project benefits (Describe overall project benefits.)

4.2.1 Benefits for Airlines

(Describe any benefits unique to the airline point of view.)

4.2.2 Benefits for Airframe Manufacturers

(Describe any benefits unique to the airframe manufacturer's point of view.)

4.2.3 Benefits for Avionics Equipment Suppliers

(Describe any benefits unique to the equipment supplier's point of view.)

5.0 Documents to be Produced and Date of Expected Result

Identify Project Papers expected to be completed per the table in the following section.

5.1

Meetings and Expected Document Completion

The following table identifies the number of meetings and proposed meeting days needed to produce the documents described above.

Activity	Mtgs	Mtg-Days (Total)	Expected Start Date	Expected Completion Date
Document a	# of mtgs	# of mtg days	mm/yyyy	mm/yyyy
Document b	# of mtgs	# of mtg days	mm/yyyy	mm/yyyy

Please note the number of meetings, the number of meeting days, and the frequency of web conferences to be supported by the IA Staff.

6.0

Comments

(Insert any other information deemed useful to the committee for managing this work.)

6.1

Expiration Date for the APIM

April/October 20XX

For IA staff use only

Date Received: : Click here to enter a date.

IA staff : _____

Potential impact: _____

(A. Safety B. Regulatory C. New aircraft/system D. Other)

Resolution: _____

Authorized, Deferred, Withdrawn, More Detail Needed, Rejected

Assigned to SC/WG: _____

Completed forms should be submitted to the AEEC Executive Secretary.
